About the Editor

D. C. Phillips (PhD, University of Melbourne, Australia) is Professor Emeritus of Education, and by courtesy of Philosophy, at Stanford University, where he has also served as Associate Dean for Academic Affairs and Interim Dean of the School of Education. He was a member of the Stanford Evaluation Consortium (directed by Lee J. Cronbach), and for several years he led its training program in evaluation of educational and social programs.

A philosopher of education and philosopher of social science educated in Australia, he is the author, coauthor, or editor of 13 books, which between them have been translated into six languages—titles include *Holistic Thought in Social Science*; *Visions of Childhood: Influential Models From Locke to Spock* (with John Cleverley); *Perspectives on Learning* (five editions, with Jonas Soltis); *Philosophy, Science and Social Inquiry: Contemporary Methodological Controversies in Social Science and Related Applied Fields of Research*; *Toward Reform of Program Evaluation* (with Lee J. Cronbach et al.); *Postpositivism and Educational Research* (with Nicholas Burbules); *The Expanded Social Scientist's Bestiary*; and *Education, Culture, and Epistemological Diversity* (with Claudia Ruitenberg). He was a member of the group that authored the National Research Council report in the United States: *Scientific Research in Education*.

In addition, he is the author of more than 120 essays in books and refereed journals, including *Educational Researcher*, *Harvard Educational Review*, *Educational Psychologist*, *Psychological Review*, *Educational Theory*, *Journal of Philosophy of Education*, *The Monist*, and *Journal of the History of Ideas*. His most heavily cited article, first published in *Educational Researcher*, is "The Good, the Bad, and the Ugly: The Many Faces of Constructivism."

He is a member (emeritus) of the U.S. National Academy of Education and a fellow of the International Academy of Education and of the American Educational Research Association; he also has been a fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford University, and Christensen Fellow at St. Catherine's College, Oxford; and he has been an academic visitor or guest lecturer at numerous universities around the world. He was president of the Philosophy of Education Society during its 50th anniversary year of 1990–1991.

Introduction

In the justly famous opening speech of Shakespeare's *Henry V*, Chorus confronts the audience with several rhetorical questions: "Can this cockpit hold the vasty fields of France? Or may we cram within this wooden O, the very casques that did affright the air at Agincourt?" Probably not, but we might come close if we exercise our imaginations! As editor of this encyclopedia, I have been faced with a parallel set of questions: Can I cram within these two handsome volumes an account of every theory and philosophical position that has been put forward in the realm of education? And can the accounts that do get included be concise, scholarly, and readable? The answer to the first of these is "certainly not," but the answer to the second, I am confident, is "yes."

It is necessary to linger over the first question and to comment on several factors that make a negative answer inevitable. First, of course, is the sheer volume of potential material; education (either formal or informal) has been a prominent concern of every known human society; and, from at least the time of Confucius in the East and Plato in the West, philosophers and others with inquiring minds have been pondering its role and nature, and reflecting also on matters that are not specifically educational but which have a bearing on it—human rights, the nature of mind, the forces driving and shaping human development from the cradle to the grave, the structure of society, the nature of virtue, the warranting of knowledge claims, and many others. To make matters more difficult (for an editor of an encyclopedia), the philosophical and educational traditions of the East and the West have diverged, and even within geographical regions, there have been philosophical diversification and concomitant misunderstandings (e.g., in the West, Continental philosophy and Anglo-American philosophy have each spawned major schools of thought). Finally, the growth of empirical research into human affairs—which of course includes education and related social phenomena—has, over the past two centuries or so, generated an enormous number of theories, hypotheses, findings, and hitherto unrecognized problems that have been the source of new speculations; and many of these have been potential candidates for inclusion in this encyclopedia.

Clearly, there is no "fail-safe" way to ensure that everything that ought to be included has been included; the hapless encyclopedia editor cannot escape making choices about what should be included and what should be cast aside. However, strenuous efforts have been made to ensure that the contents of these volumes reflect the state of the fields being discussed more than they reflect the ignorance of the editor; these efforts were made in large part by the editorial board (whose members were drawn from Canada, Germany, South Africa, the United Kingdom, and the United States), supplemented by professional colleagues and former students spread across several continents. There can be no disguising the fact, however, that the great personal interest I have had in certain theories and issues in the fields of education and philosophy has left an indelible imprint on the completed encyclopedia.

Unfortunately, the list of heart-wrenching difficulties that faced the editor is not complete. Even worse than the problems presented by the sheer bulk of material that was potentially relevant across the domain of philosophy of education and the other fields where theories have been generated were the problems presented by the three key terms in this encyclopedia's title: "theory," "philosophy," and "education."

The Concept of Education

To start, it needs to be recognized that there is far from full agreement among philosophers of education about how the concept of education itself ought to be understood. John Dewey stressed

that education was "coextensive" with life itself, and he also identified it with growth. Many thinkers working in the Continental philosophical tradition have identified education with a similar but not quite identical concept, "formation" (or *bildung*); some writers treat "education" and "schooling" as synonyms, while others insist that some things that take place in formal schooling are not educational and that some things that are educational take place outside of schools; and many scholars have pointed out that education provides individuals with the skills and knowledge to foster development of their autonomy or rationality, while others point to education's role in developing important social traits such as citizenship. All these matters are discussed at greater length in entries in this encyclopedia. As editor, I did not choose to adjudicate on these matters at the outset and adopted a liberal stance so that relevant topics would not escape the net I was casting.

Selection of the Theories

Next comes the troublesome term *theory* and its operationalization in these volumes (an even more detailed discussion may be found in the entry "Educational Theory, Nature of" in the body of this encyclopedia). The problem that had to be confronted was the variety of usages that exist here. But before discussing these, there is a prior matter that needs to be addressed: There are many topics of educational significance in the encyclopedia that seem at first blush not to involve theories in any sense at all—such as achievement gap, Montessori education, and utopias. However, the first of these names a phenomenon that has been discovered and studied empirically, and about which explanatory theories have been constructed; the second refers to a type of schooling—but one inspired by an educationist whose life's work was certainly motivated by strongly held theories; and the third refers to a category of literary works produced by authors who were strong critics of the society of their times and who usually had political or philosophical theories about the direction in which social change should occur. In short, it takes but little reflection to reveal that theories (in one or other of the term's senses) lie just below the surface of the entry titles.

But to return to the difficulties presented by the various sense of the term *theory*: The first of these, as dictionaries make clear, is what could be called the nontechnical and broadly encompassing ordinary-language sense in which *theory* is roughly synonymous with *assumption*, *guess*, or *hypothesis* (as in "My theory about the outcome of the Presidential election is . . ."). This broad, nontechnical sense of the term is made more difficult to deal with by the fact that the guess or hypothesis might be about things such as the causal mechanisms that are operating in a particular situation, about likely effects or consequences of taking a particular course of action, about policies that might be adopted to remedy a problem, or about the most fruitful way to conceptualize a problem or domain. Education-related examples of these broad uses abound: the theory that declining standards can be dealt with by the use of high-stakes testing; A. S. Neill's theory that the school dropout problem, and refusal to seriously engage with learning, can be combated by making attendance at school classes voluntary; or the theory that a major cause of the dropout problem is alienation.

Second, there is what might be termed a more technical usage—or more accurately, a set of usages—according to which the term refers to theories in the sciences. Caution is called for here, as it must not be assumed that there is one basic form that all scientific theories take, or even that there is a common function that all scientific theories fulfill. The fact is, the structure of theories and the ways in which they interrelate with scientific practice across the various physical, biological, social, and applied sciences are matters that have generated vigorous debate (especially among philosophers of science) for a considerable period of time; some of the key issues will be outlined in the following section.

It must be acknowledged that in pondering the possible contents of this encyclopedia, the decision was taken to use *theory* both in the technical and in the broad ordinary-language senses. For to restrict coverage to theories in a narrower scientific sense would, no doubt, have engendered a comforting sense of rigor, but this would have been achieved at a great cost, namely, the exclusion of many items of intrinsic interest and of great educational significance. Many theories in the broad, nonscientific senses of the term clearly are worthy of inclusion in an encyclopedia; in common with theories in the technical or scientific sense, they serve as lenses that open up educational vistas that we might not have seen—or perhaps could not have seen—without their help. However, it also must be acknowledged that there are other theories (or hypotheses, assumptions, or guesses) that—because they simply reflect human biases, are less well formulated or

supported, or deal with the picayune or with social conditions that no longer exist—are candidates for noninclusion. But as pointed out earlier, there is no algorithm to determine decisions here, and human judgment is fallible.

Mercifully, however, a principle formulated by the publishers at the outset of work on this encyclopedia gave a modicum of guidance and certainly served as a stimulus: "*We aim to produce a reference resource on theories that have stood the test of time and those that have provided the historical foundation for the best of contemporary theory and practice.*" (In fact, this was emblazoned on a large card and placed in clear sight above the editor's desk for the duration of the project.)

It is also worth noting that as this is (in part) an encyclopedia of "theory" and not of "theorists," the policy has been adopted, wherever feasible, of identifying the theory in the title of an entry, rather than using the name of the relevant theorist (these latter can be located via the Index to the volumes). This was not quite as feasible as I had first anticipated, however, for many theories are in fact inseparably associated with the individual who played a key role in formulating them; in such cases, a judgment was made about which label was most commonly used. And names of individuals are more frequently used in the philosophical entries.

Some Issues Concerning Scientific Theories

The preceding discussion signaled that there is variation across the various branches of science with regard to the form that theories can take—a theory in ecology, or Darwin's theory of evolution, does not appear to have a close family resemblance to, say, Einstein's general theory of relativity or the kinetic theory of gases. For many decades, if not centuries, the canonical account of the structure of theories (what philosophers of science often have called "the received view") was based on an analysis of theories in the physical sciences such as the latter two just mentioned, and it is interesting to speculate what form the "received view" would have taken had Darwin's work been taken as the starting point for analysis. But, for better or worse, the account that dominated throughout most of the 20th century was that a mature scientific theory consisted of a number of interrelated propositions that precisely described mechanisms, "theoretical laws," or "theoretical principles" that lay "behind" or that served to explain the empirically derived facts or observed regularities in the relevant domain. Furthermore, the theory could generate predictions about what would happen in this domain if the values of some variables were changed.

The concept of theory within the sciences was often broadened to cover two other elements: First, scientific theories often incorporated models, such as the familiar "billiard ball" model of molecules that accompanied the kinetic theory of gases (indeed there was a lively dispute about the nature of such models and about whether they were a necessary part of a theory); but whatever their status, by extension these were also often called theories. Second, the term also was stretched to refer to an overarching explanatory framework or paradigm or conceptual network that provided a way of thinking about a wide domain, and within which a number of specific theories are located (as in "Einsteinian physics," "cognitive psychology," and "behaviorism").

There can be little doubt that this tripartite "received view" of the nature of scientific theory, which in reality was an account of theory in the physical sciences, had a significant impact on the social and behavioral sciences and in education—but an impact that can now be seen to be largely detrimental. Rather sterile attempts were often made to ape the physical sciences; it was even common for scholars in the social and applied sciences, who resisted this importation of the "received view" into their domains, to quip that the social sciences and educational research suffered from "physics envy." But many others took a hard line and argued that these "softer" areas were theoretically extremely weak and even that they were to be regarded as "sciences" only as an academic courtesy. And indeed they were—and are—theoretically weak, if the kinetic theory of gases and Einstein's theory are taken as the benchmarks. Some decades ago, the respected philosopher D. J. O'Connor expressed this view in forthright prose that is worth quoting at some length:

> I tried to give an answer to the question "What is an educational theory?" My answer consisted, briefly, in sketching the standard senses of the term "theory" and showing that educational theories did not conform at all closely to these standard senses. I concluded that "the word 'theory' as it is used in educational contexts is generally a courtesy title." Naturally enough, this conclusion was not well received by all of those whose interests lie in these fields. It seemed to some critics to be, at best, unduly

> restrictive and, at worst, wildly perverse to take scientific theories as a model for theories in general and for educational theories in particular. (O'Connor, 1973, p. 48)

But the situation now is not quite so bleak, for the "received view" is no longer so widely received even as an account of theories in the physical sciences, and in addition, theoretical work in the "soft" and applied social sciences has become the focus of attention on its own terms and is no longer approached with the presupposition that it needs to resemble physics in order to be respectable.

All this being said, the field of education certainly can yield examples of theories in one or other of the three senses encompassed by the "received view" discussed earlier—more "models" and "paradigms or frameworks" than "structured sets of propositions," perhaps—and these have, by and large, been included in the encyclopedia.

It would be unsatisfactory to break off discussion of the term *theory* at this point. One other important issue needs to be pursued.

Theories *in* Education, Theories *of* Education, and Educational Practice

The starting point here is that because theories in the scientific sense give an account of the "nuts and bolts" of nature (to use Jon Elster's expression), they can be used to guide our interventions in the world—a feature noted in the old adage that "there is nothing so practical as a good theory." Unfortunately, it turns out that the relation between theory and practice is far from being as simple and direct as this might suggest. No doubt there are some educationally relevant theories that, despite the efforts of their formulators, contain areas of vagueness or lack of specificity so that they can be interpreted in many ways, resulting in multiple incompatible lines of guidance. And of course many other theories are more specific or precise. Nevertheless, it is important to realize that in *all cases*, what a theory implies about practice is open to debate. The openness of the relationship that exists between theory and practice (even when the theories are rather precisely phrased ones in domains such as psychology, that often get applied to educational problems) was noted, memorably, by William James (1899/1958):

> I say moreover that you make a great, a very great mistake, if you think that psychology, being the science of the mind's laws, is something from which you can deduce definite programmes and schemes and methods of instruction for immediate schoolroom use. Psychology is a science, and teaching is an art; and sciences never generate arts directly out of themselves. An intermediary inventive mind must make the application, by using its originality. (pp. 23–24)

Part of the issue here is what philosophers call the "is–ought" problem. Scientific statements, or theories, are attempts to describe what *is* the case, or what mechanisms or regularities lie hidden behind observable phenomena (think of the kinetic theory of gases and Darwin's theory of evolution by natural selection, to cite two spectacular examples from the natural sciences, and Piaget's theory of cognitive development). Furthermore, although it is still the focus of lively debate, a widely held desideratum for theories across the natural and social sciences is that they be value free in the sense that they must not be biased in favor of the social, political, religious, or moral values of the individuals who developed them (see the entry "Value-Free Ideal for Research: Controversies"). Consequently, if we are thinking through what *ought* to be done in some applied science or educational setting, in light of a putatively value-free theory about what *is the case* (e.g., one of those mentioned above), we run into the problem that in general there is no simple, straightforward link that allows us to leap from what *is the case* to what *ought to be done*. For the situation is that various trains of argument can be constructed that lead from the very same *is* statement or theory to quite different conclusions about what *ought* to be done in practice; where we end up depends on what value premises and other material we use in constructing the argument that actually links theory and practice—and this was part of William James's point when he noted that to generate ideas about an art such as teaching from scientific statements, "an intermediary inventive mind" was required in order to make the link, and it follows that different "inventive minds" might make links that lead in different directions. All of us are familiar with this phenomenon in our everyday lives—consider, for example, that many individuals faced with a serious medical problem seek a "second opinion," on the grounds that oftentimes two experts in the very same field will give different advice about what action ought to be taken, even when they have been provided with the same empirical evidence pertinent to

the case. Many of the encyclopedia's entries take account of all this by pointing to some of the ways the relevant theory has influenced, or has been applied to, educational practice.

So far, the focus has been on what practical implications flow from the putatively value-free, scientific-type theories that are used *in education*; but it is crucial to recognize that not all carefully developed positions that count as theories in education are, or aspire to be, scientific in this sense, nor are they to be thought of as coming from outside of the field of education and as being applied to it. (I am putting aside, for the purposes of this discussion, theories in the broader, looser sense of hypotheses or guesses.) It is my impression that theorists and philosophers on the Continent have been readier to acknowledge these as genuine theories than their colleagues in the English-speaking world.

The entities that I am referring to here can be thought of as being theories *of education*, and often, they are not value free—which is no great surprise given that the enterprise of education itself is value oriented. It has been common for philosophers to note that people need to be educated because what they *are* is not what they *ought to be*. In other words, the whole field of education has a set of core values built into it; as is made clear in numerous entries in the encyclopedia, the development of autonomy and rationality is valued, as are moral development and civic participation and the acquisition of literacy; and teaching rather than indoctrination is prized as an educational process. Thus, these theories *of education*, as well as incorporating empirical findings and the like drawn from the social and behavioral sciences, also incorporate, are based on, or are warranted by value judgments (which sometimes are explicitly acknowledged and at other times are simply assumed). In a sense, such theories do not raise the issue of how statements about what *is* the case, and conclusions about what *ought* to be done, can be linked together—for the value/normative element is actually built *into* the theory itself, together with an explicit link to the course of practical action that is being recommended. This account of theories *of* education was powerfully defended by a leading analytical philosopher of education, Paul Hirst, who contested O'Connor's narrow account of "theory" by arguing that where "a practical activity like education is concerned, the place of the theory is totally different" from what it is in the natural sciences. "The function of the [educational] theory," Hirst (1966) stated, "is to determine precisely what shall and shall not be done" (p. 40). Such a theory, he went on, necessarily draws

> on knowledge other than science; it must, for instance, draw on historical, philosophical and moral understanding as well. In particular whatever one may think of the truth claims of metaphysical beliefs and the form of justification of moral values, both these enter into the formation of educational principles and judgments. They cannot be ignored or wished out of the way. (p. 41)

Again, the issues that arise here will be pursued elsewhere in these volumes.

Modes of Philosophy

Usage of the term *philosophy* presents difficulties that parallel the ones faced in dealing with *theory*. (For deeper discussion of the following points, see the entry "Philosophy of Education," in the *Stanford Encyclopedia of Philosophy*; Phillips & Siegel, 2013). In the first place, there is a very loose usage according to which anyone who has thought deeply about a domain, or who has come to hold complex beliefs or strong biases about it (whether well founded or not), can be labeled as being a "philosopher." I have heard a professional football coach, who was noted for the innovative game plans he devised, called a "philosopher of the game"; and sometimes TV personalities who give lifestyle advice are called "real philosophers." (Such labeling is often, but not always, intended to be commendatory!) In this diffused sense of the word, there are innumerable "philosophers of education," for a great many individuals have thought relatively deeply about, or have strong and complex opinions or biases about, educational issues; parents, teachers and former teachers, school administrators, and politicians and candidates for political office are among the ranks of philosophers of education in this extended sense.

A second sense of the term—far more likely than the first to be represented in this encyclopedia—is what in other contexts I have labeled "cultured reflection on education." This category covers individuals such as the 16th-century essayist Michel de Montaigne—who had a strong interest in education and wrote in a reflective way about it but did not self-identify as a "philosopher." This category merges with another, which includes individuals

who are scientific researchers of one stripe or another, or cutting-edge practitioners, but who are nonphilosophers; sometimes, these folk step back from their research or field of practice to examine this field more broadly and, from this distance, to make insightful metacomments about it (about matters such as the adequacy of the theories that are dominant, the clarity of key concepts, the validity of research designs for putting hypotheses to the test, and the like). Einstein is a good case in point, but so is the behaviorist psychologist B. F. Skinner, as are the anthropologist Clifford Geertz and the psychologist Jerome Bruner. Making such metacomments about a field, however, has long been part of the role of philosophers—philosophers of science, for example, frequently engage in this type of work. So at the metalevel of reflection on a domain, the difference between a philosopher and a thoughtful researcher or practitioner in that domain becomes difficult to draw. Important work of this genre has found its way into the encyclopedia.

A fourth category of "philosophers of education"—one that often causes confusion—is made up of individuals who are rightly identified as philosophers (often they are among the most noted in the history of the discipline) and who have written about education but not in a particularly deep philosophical way. (Great philosophers do not always write philosophy!) The extraordinary 20th-century philosopher and logician Bertrand Russell, for example, wrote several rather feisty books about progressive education; these did not reflect his technical philosophical interests but rather were interesting reflections on the education that he and his then wife were providing in the small school they had established, and certainly, the generating of royalties was one of Russell's underlying motivations. Personally, I would also place the great empiricist philosopher John Locke's much-reprinted *Some Thoughts Concerning Education* in this category; it is a work that drew on his experiences as a man of the world, and its original form was a series of letters he wrote to a cousin giving sensible and rather down-to-earth advice about the education of her son, who evidently suffered from a learning disability.

Locke's case is particularly enlightening, for some of his technical philosophical writings—which did not mention education at all—were of profound educational significance. This, then, introduces a fifth category—works of technical philosophy that do not directly address education but that have turned out to have had great educational significance and that have been a fruitful influence on numerous professional philosophers of education and others. Locke's philosophy, for example, influenced psychologists working on problems of learning for more than a century; no doubt Friedrich Hegel, Hans-Georg Gadamer, Ludwig Wittgenstein, and John Rawls also are important examples.

Finally, there is the technical sense of the term *philosophy*, the sense that covers writings in epistemology, moral philosophy, political philosophy, metaphysics, and so forth. Much (but not all) work that self-identifies as "philosophy of education" fits comfortably here, for these works tackle directly, and in a technically philosophical manner, educational issues that have an epistemological or moral or political philosophy dimension. The work of Richard Peters, Israel Scheffler, and Nel Noddings can serve as examples.

Using the Encyclopedia

The preceding discussion dealt with some of the issues that had to be faced as the content of the encyclopedia was being selected. But another host of issues arose in organizing this content and in making it easily accessible to the reader. One matter, of course, was deceptively simple: The entries are arranged alphabetically, and there is an alphabetically ordered list of them, as is the norm for encyclopedias. The "deception" arises—as a moment of reflection will reveal—in the matter of the wording of the title of each entry (the "headwords"), for, of course, it is these titles that are alphabetically arrayed. A clear majority of the entries—I did not keep accurate score as the issue became too vexing—were renamed several times as I struggled to find titles that would allow interested readers to locate relevant items readily, that would make sense in an alphabetical listing of contents, and that would be an accurate reflection of each particular entry's content. I am sure that I did not always succeed in this apparently simple task; but I draw consolation from the fact that items of interest can almost certainly be located by way of the index, which of course lists names of individuals who are mentioned in the entries even when these do not appear in the titles.

I will refrain from tugging on the reader's heartstrings further by recounting the difficulty I faced, together with members of the Editorial Board, in selecting the categories for the Reader's Guide (RG). Suffice it to say that the domains covered by the encyclopedia—theory and philosophy—made this task

very difficult; for, as many of us know, theorists and philosophers often—and quite rightly—insist that their work cannot be readily categorized, for it deliberately transcends boundaries that too often are artificial and restrictive. As a consequence, many of the entries could be placed under three or four RG categories, and several could be placed under more, which tended to make the RG categories large and unwieldy—and these are hardly appropriate desiderata for an RG, which after all should serve to guide the reader! Eventually, however, an RG emerged with sensible categories that I am hopeful will be useful to many readers; these categories are listed in the section below.

The Reader's Guide Categories

Aims of Education

Classic Premodern Philosophers, Theories, and Theorists

Curriculum

Educational Research, Evaluation, and Testing

Equity, Rights, Social Stratification, and Citizenship

Higher Education

Learners, Learning, and Teaching

Liberal Education

Moral, Religious, Spiritual, and Social/Cultural Values

Multiculturalism and Special Populations

Organization of Schooling

Philosophy of Education: The Analytic Tradition

Philosophy of Education: The Continental Traditions

Philosophy of Education: Feminist Perspectives

Philosophy of Education: Nonwestern Traditions

Philosophy of Education: The Political Theory Tradition

Philosophy of Education: The Pragmatic Tradition

Philosophy of Science, Sociology of Science, and Epistemology

Progressive Education

Psychological Orientation in Educational Theory

Social Sciences Orientation in Educational Theory

Acknowledgments

Finally, a project of this scale could not have been brought to fruition without the help of a large number of individuals. The authors of the entries were patient and cooperative and cheerfully responded to editorial suggestions (and generally in a timely manner); several faced severe medical issues, and others dealt with family tragedies—difficulties that make their entries even more remarkable. The friends who served as members of the Editorial Board were lavish with their encouragement and with their suggestions particularly at the formative stage of the project, as were a number of professional colleagues around the world whose special expertise was tapped for guidance from time to time. The associate editor, Valerie Phillips, remained cheerful and in general unflappable as she handled the complex administration of the project, and her love of the English language made her an invaluable reader as the draft entries were submitted. Finally, the incomparable professionals on the staff at Sage made the whole process run smoothly; thanks go to Jim Brace-Thompson, and especially to Anna Villaseñor and to the senior developmental editor Diana Axelsen, whose training in philosophy at a great university in the San Francisco Bay area—familiar to us both—gave her a special perspective on the areas covered in the encyclopedia and fostered a close collegial relationship with this editor.

A

Abilities, Measurement of

Human abilities measurement is the science of quantifying individuals' capabilities for performing cognitive tasks. *Cognitive tasks* range from abstract "IQ test"–like tasks, to the kinds of academic tasks routinely assigned in school (e.g., reading, writing, science, and mathematics), to those conducted in the workplace (e.g., accounting, forecasting, and decision making). *Capabilities* are what an individual can do in a best-case situation, when alert, well rested, and motivated, as opposed to what that individual might do routinely, which is captured in the often-cited distinction between maximal versus typical performance. The importance of motivation in human abilities measurement has been demonstrated in various incentives studies that show that fairly simple incentives, such as nominal pay or suggestions that test scores might be shared with potential employers, can have dramatic effects on cognitive test scores.

The fundamental idea underlying the premise of human abilities is that there is a small, core set of capabilities that govern how well an individual can perform an infinitely broad range of tasks. Although anecdotes about human abilities undoubtedly can be traced to the beginnings of history, Sir Francis Galton and particularly Charles Spearman are credited with the modern psychometric (i.e., psychological measurement) claim that performance on tasks can be well predicted by positing a general-ability factor, which Spearman called "g," along with task-specific factors, which he called "s." In his primary mental abilities model, Louis Leon Thurstone showed that a better prediction of task performance was obtained by positing several general factors, including verbal comprehension, spatial ability, numerical ability, word fluency, memory, perceptual speed, and inductive reasoning. A reconciliation of the approaches to ability in terms of general versus primary factors was proposed by John Carroll, who reanalyzed most of the data sets on ability tests in existence and found evidence for a hierarchical model of human abilities with a general-ability factor at the top, primary abilities similar to Thurstone's at the second stratum, and even more specific abilities at the third stratum. An issue in Carroll's formulation, and in the field in general, is whether it is more useful to posit a single general factor or whether, as Raymond Cattell and John Horn long argued, proposing two broad general factors—general fluid (gf) and general crystallized (gc)—is more appropriate. The justification for the two-factor view is based on both content differences (gf is measured by abstract tasks and gc by school-like tasks) and developmental trends: Whereas gf, reflecting general thinking capabilities, peaks in young adulthood, gc, reflecting the accumulation of knowledge, peaks relatively later in life, suggesting that gf is invested to yield gc returns. Reconciliation of the g versus gf–gc positions seems to have been accomplished by the proposal of the Catell-Horn-Carroll model of the structure of human abilities, which now appears to be the most widely accepted framework for the structure of human abilities; in particular, it is the foundation for many commercial intelligence test batteries used primarily by school psychologists.

A central topic in human abilities research concerns malleability—are human abilities relatively fixed at early ages, or do they grow and improve? Support for the rank stability view (the view that the ranking of individuals remains stable even as mean scores increase) comes from test–retest studies that show high correlations between test scores measured in elementary school and those measured in adulthood, even late adulthood, such as the Scotland Mental Survey studies and similar studies conducted in Italy, Denmark, and elsewhere. Additional support comes from studies of identical twins reared apart whose abilities test scores tend to be highly correlated, as shown in the Minnesota Twin Family Study, for example. On the other hand, studies show that schooling boosts IQ scores such that each year of school leads to an additional 2 to 4 IQ points. Also, the so-called Flynn effect shows that gf scores (but not gc scores) have been rising steadily by approximately 0.2 standard deviations per decade in developed countries and that the scores in less developed countries are growing even more rapidly. Finally, there are many indications that wealth and socioeconomic status moderate test scores, so that lower–socioeconomic status individuals and poorer nations present lower test scores in international comparative studies conducted by the Organisation for Economic Co-operation and Development, and that adopted individuals show test score boosts of approximately 1 standard deviation, perhaps partly because of the enriched environment due to factors such as more sophisticated everyday family talk.

Ability measurement methods have changed remarkably little since the pioneering studies of Alfred Binet and Theodore Simon, Lewis Terman, and Spearman, and the Army Alpha examinations in the early 20th century (but see the commentaries by Susan Embretson and the commentary by Robert J. Mislevy, Robert J. Sternberg, and others on speculations on the future of ability testing). However, there have been continued calls for measuring new constructs using new methods afforded by advances in technology. For example, there have been proposals for an information processing account of human abilities, the most significant suggestion being that working memory capacity might underlie gf, a claim still being evaluated. An outgrowth of that suggestion is the finding that training working memory might increase gf, but that claim is controversial. Sternberg has been an influential proponent of new-ability measurement, particularly in advocating for the importance of creativity and tacit knowledge. These ideas have been put to the test in the development of new higher education admission tests at Tufts University, the University of Michigan, and elsewhere. Other new constructs include emotional intelligence and what have come to be known as 21st-century skills according to a recent report issued by the National Academy of Sciences and edited by James Pellegrino and Margaret Hilton. These include cognitive skills, interpersonal skills, and intrapersonal skills. In addition, there has been renewed interest in measuring response time as a part of ability measurement, situational judgment testing, and video-based testing, such as video situational judgment testing. However, perhaps the most significant development in human abilities measurement is the increased recognition of personality and its interplay with cognitive abilities. There now is a growing appreciation for the idea that schooling develops both cognitive and noncognitive skills and that the latter are more important than previously acknowledged, suggesting that measurement of noncognitive abilities is likely to receive increased attention in the coming decade.

Accountability and Standards-Based Reform

In a basic sense, accountability means nothing more than being responsible for one's actions and being willing to be answerable for them. In recent decades, however, the idea of accountability has become a central notion in new forms of governance in both the public and the private sector. This entry first examines the role of accountability in the governance and management of contemporary education, particularly in relation to standards-based educational reform—that is, the reform of education driven by setting and assessing standards of achievement. The entry then highlights some of the problems with the impact of accountability regimes on educational practice.

Accountability, Responsibility, and Management

That schools should be accountable is, in itself, a claim that few would wish to dispute. Yet there are three critical questions with regard to this:

1. To whom should schools be accountable?
2. For what should they be accountable?
3. And what form should such accountability take?

It is with regard to these questions that an important shift has taken place in recent decades as a result of the transformation of the idea of accountability from a relationship of mutual responsibility and trust into an instrument for the governance and management of organizations, including schools and the educational sector more generally. Key to this transformation has been the adoption of principles from financial accounting into a more general strategy of management and governance.

In the domain of finance, accountability has to do with the duty to present auditable accounts of the financial dealings of a business or organization, first and foremost in order to detect and deter incompetence and dishonesty in the handling of money. Accountability as a management and governance strategy works on the same principles—sometimes referred to as the idea of "management by numbers"—in that it requires data about the performance of all aspects of an organization to judge whether the organization is performing in the way it is expected to perform. Accountability as a management strategy, therefore, not only comes with a demand for total transparency but also tends to start from a position of distrust rather than trust. The burden of proof, in other words, lies with the organizations being held accountable in that they need to *prove* that they are performing according to the required standards rather than being trusted to perform to the standards. The managerial use of the idea of accountability fits well with a neoliberal approach to governing, where governments are less directly involved in the running of public services such as schools but, instead, govern such services through the specification of targets and standards that need to be met. In such a setup, regulatory bodies are tasked with the important role of assessing whether schools and other public services are indeed meeting their performance targets.

Standards-Based Educational Reform

The rise of the managerial approach to accountability has coincided with a particular approach to educational reform and educational improvement known as standards-based educational reform. The idea behind standards-based educational reform is relatively simple; it centers on setting specific standards of achievement that students need to attain. In this regard, one could even say that the idea behind standards-based educational reform is as old as education itself, as education is always done with some particular result in mind. One of the problems in the adoption of standards-based educational reform is that, over time, the specification of what it is that students need to achieve has become increasingly detailed and, more important, increasingly prescriptive. Consequently, the standards-based approach to educational governance and educational reform has significantly reduced not only the scope for schools and teachers to devise their own ideas about what their educational efforts should achieve but also their ability to tailor educational efforts to the needs of individual students. When standards are set for what students need to achieve by the end of a stage of schooling, such as primary or secondary school, schools and teachers still have an opportunity to devise different ways in which such standards can be achieved; however, when standards are set for each year, the progress students are expected to make is defined in minute detail, thus limiting opportunities for schools and teachers to make meaningful adjustments to the educational trajectories of individual students.

While standards-based reform in itself already intervenes quite significantly in the everyday practice of education, it does so to an even greater extent when it is combined with managerial approaches to accountability in which standards are the performance targets that students, as well as teachers and schools, must meet. The combination of the two thus provides a powerful mode of central control over education, which helps explain why it has become a popular approach in education policy in many countries around the world.

Problems

The combined impact of standards-based educational reform and a managerial approach to accountability has put considerable pressure on the educational system. The pressure is felt not only by students themselves but also by teachers and schools, particularly in situations where performance data—at the school level and sometimes even at the level of individual teachers—are made public. While this is often done in the name of transparency, more often than not it contributes to a culture of "naming and shaming" rather than the establishment of a culture of support for educational improvement. Perhaps the biggest problem of the combined rise of standards-based educational reform and a managerial approach to accountability has been the emergence of what in the literature is known as a culture of performativity, where *indicators* of performance become seen as *definitions* of performance, so that schools no longer aim to provide their students with a good and meaningful education but, instead, begin to focus on achieving the best possible position in comparative overviews of school or teacher performance. Because of this, and because of the more general pressure that the combined effect of standards and accountability puts on all actors in the educational system, there is a real question as to what extent these developments are contributing to the actual improvement of education.

Achievement Gap

Virtually all countries try to meet two goals for the outcomes of their schools: getting high levels of student achievement while minimizing systematic gaps in performance. Dealing with these issues simultaneously frequently presents challenges and policy conundrums. The United States—the subject of this discussion—has felt the weight of these issues where the historic pressures of segregated education have been heightened by a steady influx of immigrants. Moreover, these problems intersect with residential location patterns so that many of the challenges are concentrated within a relatively small number of school districts. Dealing with goals related to the level and distribution of performance can seldom be accomplished by using a single policy; in fact, it requires multiple policies.

Most countries find that the performance of students varies systematically with a variety of characteristics. The largest concerns generally relate to family background, as defined by income, race, and ethnicity. The motivation behind these concerns is that schooling outcomes are known to relate closely to subsequent incomes and performance in the labor market. Thus, low achievement by children that is related to family incomes and ethnicity implies an intergenerational transmission of poverty. This entry summarizes the data on current gaps in achievement and examines the explanations that have been offered for these differences. It concludes by reviewing research on some key factors—racial segregation, teacher quality, and early childhood—that could potentially have a significant impact on existing gaps and by considering their policy relevance.

Existing Achievement Gaps

It is important to understand the magnitude of achievement gaps that exist. In the aggregate, the United States has seen some convergence over time in school attainment by race and ethnicity. For the population of ages 25 to 29, there have been increases in high school completion and convergence across subgroups over the past two decades. In 1980, 89% of White students completed high school, while only 77% of Blacks and 58% of Hispanics did so. By 2012, the differences in high school attainment had been cut in half, with completion rates of 95%, 89%, and 75% for Whites, Blacks, and Hispanics, respectively.

Yet the schooling statistics also show another distributional trend: Completion of college has significantly diverged between Whites and both Blacks and Hispanics. In 2012, 40% of Whites completed a bachelor's degree or more, while only 23% of Blacks and 15% of Hispanics reached this level. The diverging completion trends are particularly important given the rapid rise in return to college over the past two decades. With the growth in the value of higher education, this differential rise in college attendance is not altogether surprising given the divergence of preparation for college.

But perhaps more important are the gaps in measured achievement of students. The United States has tracked the performance of students over time with the National Assessment of Educational Performance. This assessment has consistently traced performance at different ages and in different subjects since the early 1970s. The best comparisons are at age 17, just before students either enter the labor market or continue on to college.

The gaps in achievement are truly stunning. While there has been some historic closure, particularly in the 1980s, the current differences are enormous. The Black–White gap in math in 2011, for example, places the average Black at the 19th percentile of the White distribution. The Hispanic–White gap places the average Hispanic at the 26th percentile of the White distribution.

Explanations of Achievement Gaps

Enormous amounts of research have gone into understanding what causes these gaps. One of the first efforts to understand racial differences in achievement was the Coleman Report, an official government report issued in 1966 in response to the Civil Rights Act of 1964. The Coleman Report, officially titled *Equality of Educational Opportunity*, was widely interpreted as concluding that families were the most important influence on student achievement, followed by each student's school peers; schools had little influence on achievement. However, that analysis has been heavily criticized for a variety of analytical reasons. Overwhelmingly important for the purposes here, however, is that it did not have good measures of differences either in school quality or family backgrounds. Indeed, subsequent attempts to sort out the impacts of families, schools, and peers have foundered on similar problems.

We do know that common measures of school quality—spending or other characteristics—are not closely related to achievement. On the other hand, variations in teacher effectiveness are important, reinforcing the general presumption that schools have a strong impact on students. It is just that the classic input measures of teacher quality are not very useful.

In reality, given our current knowledge, it is simply not possible to measure the relative importance of the various underlying causes for the existing gaps. We know that student achievement is strongly related to family background, but little attention has been given to how family background should be measured if one is looking for the causal structure. It is clear that we would like to eliminate the racial and ethnic gaps in achievement, both because of equity goals and because of the impact of unfulfilled human capital possibilities. But looking at policies to do so is not the same as knowing the causes of the existing gaps.

Racial Segregation in U.S. Schools

Over a long period of time, the United States has wrestled with problems related to racial segregation. Before the 1954 ruling of the U.S. Supreme Court in *Brown v. Board of Education*, a number of southern states had de jure segregation of schools, or segregation established by law. The Court ruled that this led to an inherently unequal system of education and called for desegregation of schools. This ruling led to a long series of actions, sometimes related to further Court decisions, that moved toward breaking up past racial concentrations. The movement away from de jure segregated schools was balanced by de facto segregation of schools outside the South, where racial concentrations were the result not of legal restrictions but of residential patterns coupled with school assignment policies.

The research most directly related to questions of how racial concentration relates to achievement gaps focuses on whether peer racial composition, as opposed to desegregation actions per se, affects achievement of Blacks as well as other demographic groups. While this has been a difficult issue to research, the available evidence suggests that Black achievement is harmed by having schools with higher concentrations of Black students. (Current evidence does not indicate similar impacts for Hispanic students.)

Nonetheless, because racial segregation in schools largely results from separation in residential location across jurisdictional lines, there are few legal or policy recourses that would lead to lessened racial concentrations. In part this is the case because, since the 1970s, the courts have taken an increasingly narrow view of actions toward reducing school segregation. In particular, consideration of interdistrict remedies was increasingly ruled out by the Supreme Court. Perhaps the final limitation came in 2007, when the Court even struck down voluntary race-conscious plans operated within individual districts in cases involving Seattle, Washington, and Louisville, Kentucky.

Teacher Quality

Perhaps the strongest and most consistent finding of recent research is the importance of teacher quality. The early work on teacher quality focused on measurable characteristics and background factors of teachers, such as experience or type of training. The analysis of teacher effectiveness has largely turned away from attempts to identify specific characteristics of teachers. Instead, attention has focused directly on the relationship between teachers and student outcomes. This outcome-based perspective, now commonly called value-added analysis, takes the perspective that a good teacher is simply one who consistently gets higher achievement from students (after allowing for other sources of student achievement, e.g., family influences or prior teachers).

In a series of studies since 2000, outcome-based estimates find substantial variation in teacher contributions to achievement, supporting the interpretation that the earlier work simply had poor measures of teacher quality. For example, available results imply that having a teacher at the 75th percentile as compared with the 25th percentile of the quality distribution would move a student at the middle of the achievement distribution to the 58th percentile (in one academic year). The magnitude of such an effect is large relative to the typical measures of Black–White or Hispanic–White achievement gaps described previously.

While there is little evidence that teacher quality varies systematically with student characteristics (race, ethnicity, or income), the results suggest that improving the quality of teachers for disadvantaged groups could close substantial parts of the existing achievement gaps.

Early-Childhood Education

A recent focus of policy discussions is preschool education. There are three arguments for why broad provision of preschool education is a good idea. First, the problems of disadvantaged children at entry to school have received increased attention, particularly with the availability of new longitudinal data for early childhood. The deficits in preparation of disadvantaged children are significant. For example, evaluations of the vocabulary of disadvantaged children find that they have been exposed to dramatically less vocabulary—more advantaged children at age three had vocabularies that were four times as large as disadvantaged three-year-olds. Moreover, the quality of parent–child communication was vastly different. These differences in preparation have potentially lasting effects on student outcomes.

Second, a variety of conceptual arguments for early investments in human capital—most notably by Nobel laureate James Heckman and his colleagues—have received scholarly and policy attention. They suggest that investments made early in life enhance learning later in school and even into careers.

Third, key studies with strong research designs have supported the efficacy of preschool education. The most well-known is the Perry Preschool Program, but others, such as the Abecedarian Program and the Early Training Program, also provide important evidence.

For these reasons, it is natural that discussions of preschool enter into the education policy debate and into judicial proceedings and judgments. There are reasons to be favorably disposed to instituting expanded preschool programs for disadvantaged students. The idea has been to supplement what goes on in the home in order to provide stronger educational development. Such preschool investments recognize that it is easier to remediate earlier rather

than later. At the same time, the limited number of models that have been evaluated provides uncertain guidance about the design of effective programs, particularly programs that reach male children.

Some Conclusions

Achievement gaps, particularly by race and ethnicity, have been large and persistent in the United States. The continued existence of these gaps is incompatible with widely held views of equity for society, because they indicate a persistence in economic disadvantages.

Correcting these problems, however, has proven difficult. First, there is genuine uncertainty about governmental policies that will systematically raise student achievement. Second, policy goals invariably include raising achievement of all students in addition to closing achievement gaps. If closing gaps meant simply redistributing good schools from the more advantaged to the less advantaged, there would be obvious political conflicts and there would be a conflict with goals to increase all achievement.

One policy that would potentially improve minority achievement, particularly of Black students, without harming White students would involve lessening the concentrations of Black students in segregated schools. The range of potential policies is nonetheless very limited because there is little ability to move students across jurisdictional lines, where most of the segregation exists.

Improving teacher quality, particularly for minority students, is one policy that holds promise. The best way to do this remains somewhat uncertain, although there are many ongoing potential policy initiatives that might solve this. The largest problem is that teacher effectiveness is not closely related to common measures used to assess teacher quality, such as experience or graduate training. Thus, it is difficult to regulate better teachers, and moving toward improvements demands being able to evaluate teacher effectiveness directly. This remains a topic of much current debate and research.

Finally, a particularly attractive policy is providing improved early-childhood education for disadvantaged students. Because education in the home and through other early experiences currently favors more advantaged students, better preschool experiences of disadvantaged students would act to equalize early opportunities. This would tend to improve their preparation for school and to close achievement gaps without harming the more advantaged students. The policy issues in this realm relate to finding the best way to provide and pay for this early-childhood education.

Achievement Motivation

Motivation is a psychological construct that explains the nature, strength, and persistence of behaviors. *Achievement motivation* concerns motivation in contexts in which performance standards apply and outcomes can be judged as successes or failures. Typical contexts include schools, athletic fields, the workplace, the stage, and even social situations. Success and failure may be defined variably, for example, as meeting a personal goal, achieving recognition or a reward, or winning a competition. Success for a pianist might be measured in the length of applause, for a hostess in the amount of food the guests

consume, for a student in the grade on a test, and for a surgeon in whether a patient survives.

Theoretical Frameworks

Theories of motivation have been generated to help explain, predict, and influence behavior. Those that focus on achievement vary in their assumptions about whether the source of motivation is in the individual or in the environment, how malleable it is, how it is measured and how it is influenced.

In the 1950s and 1960s, David McClelland pioneered the field of achievement motivation, stipulating that, as a consequence of parenting in early childhood (e.g., supporting autonomy, encouraging achievement striving), individuals develop a stable disposition or trait, which he referred to as "need for achievement" (nAch). Individuals high in nAch possess a strong motive for success and seek challenges. Low nAch is associated with selecting very easy tasks (to minimize the risk of failure) or very difficult ones (to avoid embarrassment from failure). His conceptualization of achievement motivation shared with psychoanalytic theory the notion that motivation is not conscious and therefore needs to be assessed with projective tests.

In stark contrast, behaviorists who became prominent in the early 1960s conceptualized all motivation entirely in terms of observable behavior and explained all behavior in terms of previous reinforcement contingencies—what Edward Thorndike referred to as the "law of effect." According to this theory, individuals exhibit a particular behavior in achievement or any other setting because they have been reinforced (rewarded) for that behavior in the past. Accordingly, students who are rewarded (e.g., with good grades or praise) for working hard on school tasks and for persisting when they face difficulty will continue to work hard and persist in the future.

Reinforcement theory was originally derived from drive theories, which assumed that reinforcement necessarily involved the reduction of basic biological needs (e.g., hunger and thirst). A parent's praise, for example, might have taken on reinforcement properties by having previously been associated with food and the reduction of hunger. Difficulties in explaining the effectiveness of a wide range of outcomes that appeared to influence behavior led theorists to drop drive reduction as a factor. Reinforcement theorists today make no claims about particular qualities of reinforcements. Any consequence of a behavior that increases the likelihood of its future recurrence is, by definition, reinforcing, and any consequence that reduces the likelihood of its recurrence is punishment.

Behaviorism is considered mechanistic because it is not concerned with beliefs, feelings, aspirations, or any other psychological variable that cannot be directly observed. The theory has clear implications for how motivation is conceptualized and measured. Motivation is not considered a quality of the person but, rather, is conceptualized as a set of behaviors and their contingencies. Any attempt to influence motivation would involve rewarding desirable behavior and punishing or ignoring undesirable behavior.

Many achievement motivation theorists find such mechanistic assumptions about behavior unsatisfactory and, instead, have explored psychological variables that are not directly observable. Cognitive motivation theorists do not rule out external reinforcement as a cause of achievement behavior. They claim, however, that cognitions (beliefs) such as expectations mediate the effect of rewards. In addition to personal histories of rewards and punishment, beliefs are based on many factors, such as observations of the consequences for others when they behave in a particular way or, even simply, what they are told about what they can expect. When teachers call attention to the consequences of students' behavior ("Table 3 can go to recess because everyone is sitting quietly") and when they promise rewards ("If you finish all your work before recess, I'll let you play on the big kids' yard"), they are using cognitive motivation theory. They are attempting to influence behavior by affecting expectations about the consequences of desired behaviors.

Cognitive motivation theorists focus on a variety of beliefs related to achievement behavior. Self-efficacy theory focuses on expectations for success. Self-worth theorists study the ways in which individuals' beliefs about their competence in performance domains affect their behavior. Locus of control theorists have demonstrated the role of perceptions of control over outcomes. If a performer believes that the judges are biased against him, for example, he might believe that success is not really within his control and, therefore, not exert much effort. Attribution theorists fine-tuned locus of control theory by differentiating among specific controllable and uncontrollable causes of outcomes (e.g., luck, ability, effort, help, etc.) and examining the effects on behavior of particular causal attributions.

Beliefs about achievement are malleable, and because beliefs are to some degree situational, cognitive motivation theorists sometimes measure them in specific situations (Do you expect to succeed on this math test?) or domains (Are you athletic?). Cognitive theorists design interventions that are aimed at changing maladaptive beliefs, for example, by trying to convince individuals that they can, in fact, succeed if they exert effort.

John Atkinson introduced values into achievement motivation theory. According to his expectancy *x* value theory, exerting effort and persisting on a task require more than expecting to be able to complete it; the task must also have some value attached to it. Atkinson conceptualized value narrowly in terms of pride in success. Other theorists have considered values more broadly, such as in terms of how important achievement in a particular domain is to one's self-concept and how useful particular kinds of achievement are perceived to be. Researchers working from an "expectancy *x* value" theoretical framework, therefore, measure students' perceptions of the value of success or other rewards in efforts to predict or change behavior. Attribution theorists, mentioned above, also assume the importance of pride in achievement-related behavior, finding that attributions for success and failure affect pride and other emotional reactions differently, and the emotional reactions, in turn, affect subsequent behavior. For example, success attributed to personal effort produces pride that promotes future effort, whereas success attributed to luck yields surprise rather than pride, which may not promote future efforts.

Intrinsic motivation theorists are also concerned with emotional as well as cognitive aspects of motivation. Intrinsic motivation theory is based on the assumption that humans are inherently motivated to develop their intellectual and other competencies and that they take pleasure in their accomplishments. Part of the value of achievement striving is the intrinsic pleasure one experiences from achieving higher levels of mastery or understanding. Intrinsic motivation is typically measured by observing people's voluntary activities. Thus, to assess students' intrinsic motivation to read, researchers might find out how much they read on their own, when there are no external consequences. Or they might give them several activities to choose from and observe whether they do one involving reading. In interventions designed to increase intrinsic motivation, the context or the task is changed in ways that are known to foster human beings' intrinsic motivation, such as ensuring that the task is challenging but not too difficult and providing some choice.

Self-determination theorists add two basic needs—to feel self-determining (having some control over one's behavior) and to feel socially connected—to the need to feel competent, which is central to intrinsic motivation theory. According to this theory, people do not function effectively in any achievement context that fails to meet any of these three needs. Self-determination theorists thus study the conditions that support individuals' feelings of competence, control and social connectedness, and design interventions that create those conditions.

Recently, goal theorists have pointed out that people engage in the same behavior for different reasons and that the reason for engaging in a task is just as important as the level of effort, degree of persistence, or any other observable behavior. For example, the goals of learning, mastering, or understanding (referred to as "mastery goals") have been found to promote intrinsic motivation and challenge seeking better than the goals of achieving extrinsic rewards or recognition ("performance goals"). According to goal theorists, interventions designed to change maladaptive behaviors and increase learning require changing goals.

In summary, achievement motivation theories are based on different assumptions about factors that affect behavior in achievement-related contexts. They are not, however, mutually exclusive. It is highly likely that parenting in early childhood affects individuals' general disposition to be achievement striving, that all individuals take some natural pleasure in a feeling of mastery or competence, and that beliefs about the likelihood of effort leading to success affect effort on tasks, and so on. Together extant theories of achievement motivation suggest that behavior is affected by both the setting (e.g., reward contingencies, support for autonomy), as well as by both malleable (e.g., expectancies for success) and more stable (need for achievement) factors internal to the individual.

Activity Theory

Activity theory (AT) focuses on how culture and history shape individual consciousness and the organization of collective activity. Its roots lie in Marxist philosophy and the Soviet psychology of the 20th century. Like Marxist philosophy, AT foregrounds the role of material, goal-directed activity in shaping human consciousness. The core ideas of AT trace their origins to the writings of Lev Vygotsky and his followers in the early 20th century, including A. N. Leont'iev, Alexander Luria, Vassily Davydov, S. L. Rubinstein, and P. I. Zinchenko. Current AT focuses on the importance of accounting for multiple and interacting activity systems and partially shared objects.

Relevance to Educational Theory and Philosophy

AT arose as a critique of two widely circulating theories in Russian and early Soviet psychology—behaviorism and introspectionism. Vygotsky criticized behaviorism for focusing only on what animal and human behavior have in common, rather than what distinguishes them. He argued that psychological theories should explain instead how voluntary functions, such as attention, memory, and problem solving, arise. He posited that human beings employed cultural and historical tools to direct control over behavioral processes and to organize activity. Such control and organization are evident whenever people carry out joint action.

Vygotsky also criticized introspectionism, the idea that understandings of human mental functioning should be derived from introspection. He argued that psychologists should not analyze thinking apart from human activity, since these activities play a central role in individual development. Vygotsky argued that before a process appeared on the "psychological plane," it first had to appear on the "social plane," in collective activity. He termed this the *genetic law of cultural development*. A distinguishing feature of the Vygotskian framework is the centrality of culture and cultural mediation understood as a uniquely human environment imbued with artifacts and practices of previous generations and changed by their use in goal-directed human activity.

AT's significance arises not only from its critiques of psychology but also from its concern with *praxis*, or practical human activity to transform the world. Vygotsky and his collaborators engaged in clinical and educational endeavors directed at improving the conditions of young children, children with disabilities, and adults who had suffered from brain injury. More recently, scholars have used AT to organize and analyze educational settings in schools, informal learning environments, and workplaces; to reveal and analyze the cognitive demands of work often judged to require limited knowledge; to design sociotechnical systems; to study knowledge production and change in organizations and in processes of professional development; and to guide radical forms of psychotherapy. Recent scholarship has also extended the use of AT as a framework for analyzing and organizing social change. It has been an especially useful framework for scholars studying how to draw on cultural, racial, or linguistic differences as resources for teaching and learning. In particular, this emphasis on conceptualizing diversity as a resource has helped generate new models of educational intervention that build on repertoires of practice within nondominant communities to open new possibilities for activity.

Core Constructs of AT

The foundational idea that individuals develop in relation to the systems of activity that constitute an individual's life forms the basis of the constructs that animate AT.

Analysis of Levels of Activity

In contrast to theories of learning and development that presume that activities are static while individuals change, AT posits that systems of activity are also changing. This led Leont'iev (1978) to argue that activity must be analyzed at multiple levels, which he characterized as the levels of activity, action, and operation. In this scheme, activities are collectively organized and can be characterized in terms of their motives. Actions are an intermediate level, analyzed in terms of the objects of individuals, and operations are a means toward accomplishing goals. Many operations become unconscious or automatic through repetition.

Subsequent theorists have offered related, but distinct, formulations of the concept of levels of activity. Yrjö Engeström's (1987) theory of learning by expanding, for example, proposed a method

of analysis of activity in terms of tools or artifacts, rules, and division of labor. Learning by expanding focuses attention on development as a concerted, collective effort to transform activities in ways that expand possibilities for action by analyzing contradictions or tensions within and across activity systems. Engeström and colleagues have developed these ideas through formative interventions in the form of change laboratories where participants, local practices, dialogue, and participants' interpretations matter. In these change laboratories, dialogue and sustained relationships set the foundation for the generation of novel solutions, problem solving, and transformation. Change laboratories have been used to facilitate improvements to hospital care and public services in Scandinavia.

Within developmental psychology, Barbara Rogoff (1995) proposed an analysis of development in three "planes": (1) the individual or psychological, (2) the interpersonal or group, and (3) the community levels. Consistent with earlier AT formulations, Rogoff's theory posits that development entails the ongoing, mutual constitution of development across these planes, separated out only for analytical purposes to privilege an understanding of particular human activity. Accordingly, people inherit and make use of practices invented by others and then change those practices in participation.

Mediation

The focus on goal-oriented action within AT gave rise to inquiry into the means for accomplishing action. Vygotsky (1987) referred to "psychological tools" as means linked to the higher mental functions of directing attention, constructing memories, and solving problems. These tools encompass all manner of signs and systems for creating and transforming meaning: language, gesture, systems for counting, mnemonic devices, mathematical symbol systems, diagrams, maps, drawings, and so forth. The introduction of such tools into the flow of activity both facilitates and transforms object-oriented activity.

For activity theorists, the capacity of human beings to use such objects to regulate the self is an important function of psychological tools. These include the use of tools to aid not only in problem solving but also in remembering events and focusing one's attention. A person can draw on other kinds of tools, such as projections of a future self engaged in particular kinds of activity (as in *prolepsis*), to construct identities (Cole, 1996).

Genetic Method

AT emphasizes the *process* of development. A key aim of analysis is to trace the genesis of particular psychological processes within activity. In AT, relations among persons, activities, and tools are not considered at just one moment in time; rather, their development over short and long time spans is examined. Cultural–historical analysis within AT encompasses the history of the species (phylogeny), the cultural history of social groups, the history of experience of each person (ontogenesis), and microhistory of events that are in the immediate context of a person's life (microgenesis). In contrast to some images of development in psychological theory, experiences of development over time are understood to entail dynamic processes full of upheavals, sudden changes, reversals, boundary crossing, even destruction and breaking away from activities.

One approach to studying how tools mediate activity is the method of double stimulation (Vygotsky, 1978). An investigator using this method presents a person (e.g., a child) with a stimulus or problem to solve that is hypothesized to be outside his or her capabilities to solve. The investigator observes how this person approaches the problem and then presents to the person a tool meant to aid in problem solving. The introduction of tools to aid in problem solving can construct what Vygotsky called a *zone of proximal development*, "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers" (p. 86).

Criticism and Challenges to AT

One critique of AT pertains to the idea of goal-directed action. Lucy Suchman (2007) has pointed out that objects and plans do not always precede or control activity; in fact, reasons and purposes are often retrospective constructions rather than guides to activity (see also Lave, 1988). These theorists argue that goals or purposes are better understood as resources in activity—akin to other kinds of artifacts and psychological tools—rather than something special that precedes action. Others point out that much action is habitual rather than consciously goal directed.

Another critique relates to the monism of traditional Marxist conceptions of activity, that is, that reality constitutes a singular whole. Some scholars

from within the tradition of cultural–historical AT emphasize the hybridity and heterogeneity of cultural tools within activity as key resources for learning by expanding. Some also emphasize the variation within and across cultural repertoires for participating in activity as sources of heterogeneity in activity. Drawing especially on the work of Mikhail Bakhtin (1981), these theorists describe *multivoicedness*—the tension among different voices and perspectives on activity—as generative of change and expanded possibilities for action. Actor–network theorists critique monism in AT, because it fails to provide a means for analyzing heterogeneous actors in complex networks. Actor–network theory posits that the social and material are symmetrical forces within human activity, brought together into assemblies or networks of linked people, artifacts, and practices (Latour, 2005).

At present, a key challenge for AT is interdisciplinarity. The study of activity necessarily draws on perspectives from anthropology, sociology, history, economics, and other human sciences. Yet it is most well developed at present within the fields of psychology and human–computer interaction. Historically informed accounts of activity are largely absent, which is a problem given the centrality of history to AT. As the study of activity expands to encompass more disciplinary perspectives and methods, scholars within AT argue that a challenge will be for AT to remain a coherent framework for analyzing activity rather than an eclectic grouping of multiple theories.

Actor–Network Theory: Bruno Latour

Actor–network theory (ANT) is an approach that attempts to capture the complexity of the social world by tracking the relations among human and nonhuman actors (which might be other living things, objects such as machines, or ideas); it examines how scientific knowledge arises through the interactions between scientists and researchers and the social and the natural contexts on which they act. It is most closely associated with the French thinker Bruno Latour. It has its roots in the sociological study of science, but in taking in other objects of study (including politics, law, technology, and religion), it has developed into a philosophical enquiry into our "modes of existence" that poses considerable metaphysical challenges to conventional accounts of our world.

From one perspective, Latour's project is one of alternative historicization. He does not seek to understand science in terms of a conventional heroic narrative, one that is teleologically directed in the sense that, armed with prior knowledge of the outcome, it recounts how this successful discovery of transcendent truth came about; rather, he builds up a detailed description of how scientists operate as they go along, facing challenges and choices and, in the absence of a route map, not knowing what obstacles or dead ends will confront them. In trying to understand science in action, one needs to observe scientists at work in the sites in which their knowledge is produced. For Latour and his collaborator Steve Woolgar, this was a neuroendocrinology laboratory in California, but the object of study might be fieldwork in the Amazon forests or, historically, Louis Pasteur's part in the discovery of microbes.

Science in action arises out of controversies (Does the Higgs boson exist?), and ANT seeks to describe the process whereby these matters of concern are (or are not) transformed into matters of fact. ANT is as interested in failure as it is in success. The laboratory gathers scientists and the equipment they have built to run their experiments, but it is full of pieces of paper as well—grant applications that keep the project funded, scientific journals bearing on matters of concern, diagrams, protocol books, photographs, and so on, all of which must be acknowledged as playing their inextricable part in the process of generating facts. In particular, Latour and Woolgar draw attention to "inscription devices," equipment devised for experiments that records experimental data and thus transforms the behavior of matter into written documents. Realist accounts of science tend to elide this representational element and the considerable work it does in both generating and sustaining those facts and to assume an unmediated insight into reality itself. For Latour, what we take to be real is the effect of those representations, and our sense of what we call "reality" changes as new representations are developed. Thus, Latour does not start from the position that the objects we study are stable and taken for granted; rather, he seeks to understand the processes by which they become stabilized, at least *relatively* stabilized, to the extent that they can be taken for granted.

Influenced by ethnomethodology, one important principle of ANT is the requirement to respect the metaphysics of the actors involved in what you are studying. Scientists are not the only actors in this process; crucially, and controversially, what Latour calls "non-humans" are actors as well and are granted agency. Anything that modifies a state of affairs, that makes a difference, is an actor. The failure of a piece of equipment or the puzzling appearance of an unexpected phenomenon in a photograph can make scientists do something; conversely, scientists can devise equipment (e.g., the large hadron collider) that makes pieces of matter do something that renders them visible to their inscription devices and also, as a consequence, real. This is not to endow nonhumans with consciousness or intentionality; for Latour, "make do" expresses the range of metaphysical shades that can exist between full causality and sheer inexistence. A second principle is that of symmetry: In advance of the enquiry, the investigator must not make assumptions that endow one type of actor with ontological privilege at the expense of another in respect of size (the very small may turn out to be more powerful in its effects than the very large), materiality, its status as human or nonhuman, and so on.

In not privileging the human over the nonhuman, ANT challenges the conventional distinction between subject and object. The laboratory is just one site where humans and nonhumans are gathered together in a context-specific web of associations and their identities are significantly fused—hence the en-dash (–) in actor–network theory. Pasteur developed procedures that rendered visible the agency (and existence) of microbes, but in an important sense, microbes play a part in the network (what Latour called in the title of one of his books *The Pasteurization of France*) that makes the Pasteur we are familiar with, and though long dead, Pasteur remains an actor in the health regimes engineered to control their effects that are still in place. An actor–network is made to exist by these attachments, and the more attachments it has—and the more resistant these alliances are to hostile scrutiny—the more powerful it is. Against the Cartesian definition of the ego ("I think, therefore I am"), Latour offers "I am what I am attached to." However, an actor–network is only as good as its weakest attachment, and that is what makes the difference between success and failure, between Pasteur and his rivals.

It is in this network of mediations that the scientific fact emerges as painstakingly *constructed:* etymologically, facts are "things made." This claim led to many attacks on Latour and his associates in the so-called science wars, to which Latour was happy to respond (often with a playful sense of humor

lost on his opponents), though they did lead him to be critical of the sociologistic emphasis of his early work. In explaining science, you cannot reduce it to the social—to do so is at the expense of taking the social and its key terms (e.g., power) for granted. For ANT, no thing can be reduced to some other thing in this way, for to do so is at the price of taking that other thing as simple and unproblematic—a notion that ANT asks you to challenge on principle (the theory takes on its specific identity from whatever actor–network it is attached to). Things (including ANT) do not exist "in themselves" as isolated quasi-atomic individual entities beyond analysis (Latour likes to appeal to the Germanic etymology of the word *thing* as an assembly that is to decide a disputed matter). Every "thing" is always already an aggregate that is significantly modified when brought into an association with something else that acts as a mediator and effects what Latour terms a *translation*. Explore the social and the scientific together under ANT, and both will be transformed. Rather than the distinctive "objectivity" of science being taken for granted, it is that very objectivity that is to be explained. Scientific facts are indeed constructed in the local circumstances of the laboratory, but if the network that generates them is robust in all its associations, those facts can be transported to any time and any place and so can claim to be *universal*. Latour uses the metaphor of the "black box" for such a fact: Like a computer or a television, if it does what it is supposed to do, you do not feel the need to open it up and find out just how complex its components and their interactions are. The so-called social sciences in their own right may aspire to the black boxes of the sciences and the stabilization they represent, but though sociology would like the social to be one, from the perspective of ANT, the social cannot be used as a cause to explain anything. Rather, the social is the consequence of the attachments, the hybrid network of associations of humans and nonhumans, ANT would trace. For ANT, the social sciences get it the wrong way round, taking for granted the very "thing" that is their task to explain—how associations are formed.

Nonetheless, condensed hybrid aggregates, "collectives" such as society or nature, operate powerfully on humans. A collective provides a shared definition of a common world, and such collectives underpin disciplines. Latour (2005) says of disciplines that "each has chosen to deploy some sort of mediator and favored some type of stabilization, thus populating the world with different types of well-drilled and fully formatted inhabitants" (p. 258). This leads to his theory of modes of existence. There is not one world out there but a plurality of worlds (politics, law, religion, science, the economy, etc.)—multiple regimes of truth operated in accordance with distinctive types of reason that present to us multiple modes of existence we inhabit. None of these is reducible to any other, though strenuous attempts to do so are made. In particular, modernity is characterized by its attempts to "purify" the hybrid collectives—society and nature. From the perspective of ANT, this cannot be done, and the project of modernity never got off the ground in the first place. This is not to make us postmodern: Rather, in the title of another of Latour's books, *We Have Never Been Modern.*

How does ANT relate to educational theory? In his dialogue *Meno*, Plato uses a set of exchanges about geometry between Socrates and a slave to suggest that there is no such thing as learning, only a remembering of knowledge that was always already there in our immortal souls before birth. However, for ANT, geometric deduction is not hardwired into our brains, but it is a historical construct involving the development of technologies of representation (the lettered diagram) through which Greek mathematicians could devise compelling proofs by tracking exact equivalences through successive stages of argument (see Netz, 1999). So while Pythagoras's theorem is the historical product of a particular time and place, other people can learn how to use the diagrams and techniques the Greek mathematicians developed, so that the proof can be demonstrated any time and at any place and is, theoretically, a universal fact. For ANT, like all forms of knowledge, these are *transferable* skills, skills that can be "carried across" time and space—but only as long as the networks of transmission that carry the techniques associated with the proof (schools, curricula, etc.) are not broken.

Addams, Jane

Jane Addams (1860–1935) is best known for her contribution to the practice of social work in the United States; her efforts at Hull House (part of the Settlement Housemovement) have become famous, and she was given international recognition when she was awarded the Nobel Peace Prize in 1931. However, it is important to understand her social work as part and parcel of her pragmatist educational and social theorizing. Working alongside—and thinking together with—a group of educated women activists (e.g., Frances Kelley and Charlotte Perkins Gilman), as well as with the scholars of the Chicago School (e.g., John Dewey and George Herbert Mead), Addams was a pragmatist feminist whose commitment to plurality without antagonism was the centerpiece of educating (both adults and children) for democracy and freedom, and whose innovative understanding of ethics as utterly social was a springboard for social progress. These themes are explored in this entry.

That Addams's work is legitimately philosophical has been established in recent decades by a host of scholars who recognize the innovative quality of her ideas as well as the impact she had on her pragmatist contemporaries. It is important to note as well that she was recognized as a philosopher (as well as an activist) in her own time. Contemporaneous reviews of her *Democracy and Social Ethics* suggest that Addams's writings were interpreted philosophically. Furthermore, we know that Dewey spent significant time analyzing that work in his 1902 course on sociology of ethics and, in 1932, quoted Addams in his own final statement of *Ethics*. There he noted that Addams's formulation of a social ethics as a springboard for social progress had been groundbreaking. What bound Addams and the later Dewey was the insight that ethics is not an abstract field rooted in social ideas but in life lived in social interaction.

Given that Addams was a philosopher, she was one of a very specific kind emerging in her time and place: a pragmatist feminist. A pragmatist sooner than Dewey, living in and through the first wave of feminism, Addams wrote in an idiom that brought careful, experience-based analysis to bear on immediate social issues from poverty to immigration, to child labor, and to war and peace. While some of her writings are titled to betray their philosophical intent (e.g., *Democracy and Social Ethics*), many are not (e.g., *The First Twenty Years at Hull House*). But all of her work instantiates philosophy as an embodied, emplaced activity.

Inhabiting a female body in an age that constrained female bodies physically, medically, and culturally prompted Addams's feminist wrestling with the contributions to the social good that are possible in the face of such constraints. Over time and travel to Europe and back again, across psychological terrains of depression and immobility, with a dual recognition of both her (class and educational) privilege and her (gender) oppression, Addams developed, in her Rockford Academy commencement speech, the insight that women can and should be "bread givers," or people who provided emotional, physical, and spiritual nourishment to others. In thought and action foreshadowing aspects of Nel Noddings's *Caring* and Sara Ruddick's *Maternal Thinking*, she articulated and valued without apology a woman's perspective—without insisting that it be essentialized or limited to gender categories. Her category of "sympathetic knowledge," involving the reciprocal exchange of ideas, relies on reason without denying feeling, on relation without obliterating personal responsibility, and on contextuality without sidestepping the value of knowing.

Addams's pragmatism emerged in response to a progressive zeitgeist that located meaning in the consequences of action. What Charles Peirce and

William James could identify as the justification of meaning by results in action, Addams would enact and expand. As noted, she came to her full pragmatist concept of democracy, ethics, and education early, unconstrained by the history of philosophical conversation (specifically Hegelian idealism) that delayed Dewey's understanding of ethics as rooted in social experience. She resolved the apparent dichotomy between philanthropic giving and receiving in "The Subjective Necessity for Social Settlements," locating the philanthropic impulse in democratic living, in the sense of looking out for one another, and in the insistence that those who would be affected by any decision must be part of the decision-making process.

In *Democracy and Social Ethics*, Addams characterized democracy as a rule of living as well as a test of faith. When Dewey later described democracy as a mode of associated living, it is difficult not to hear echoes of Addams. Addams champions "lateral progress" as social gains achieved in reciprocal communication and held in common; this is the marker of democratic society. Her formulation represents not mere equality, nor political franchise, but something far more complex.

For Addams, education was both a means to achieve common ends and an end in itself. Through the reciprocal exchange of ideas among differing individuals—cast as play for children, as meaningful work and shared discussion for adults—cooperative intelligence is achieved. Democracy, as a way of living and as a mode of political value and organization, finds fertile ground here.

Both Addams's feminism and her pragmatism can be characterized as critical because she lived diversity as she thought about it. She recognized the play of privilege as a feature and function of diversity and employed that recognition to frame challenges to taken-for-granted power structures. Addams's Nobel Prize–winning pacificism was one such challenge and so was Hull House. Viewed as a philosophical design experiment rooted in the constructive possibilities of pluralism, Hull House served to demonstrate the possibilities for living democracy, effecting education, and "revivifying" the social life of Chicago at the turn of the 20th century. Addams's work at Hull House and her philosophic and social writings can be understood as mirror images working out these elements in both thought and action.

Adler, Mortimer, and the Paideia Program

Mortimer Adler, professor, philosopher, and educational theorist, was born in New York City in 1902. He left school at age 14 to write for newspapers and initially enrolled in Columbia University to improve his writing. Because he never passed the swimming test, he never earned a baccalaureate degree, but he did eventually earn a PhD from Columbia University where he studied with John Dewey. Adler eventually repudiated Dewey's faith in progress and in science, positing instead the argument that while human situations may change, human problems remain the same. For education, then, we should look to the ancients and to philosophy rather than to fashion and science.

It is not surprising, then, that "Mortimer Adler" and "great books" are often considered synonymous categories. Adler believed that the classics are the foundation of a good education for all people because they *pass down* the "great ideas." Reading the great books develops ethical, socially responsible citizens who have in the great ideas the basic tools for living a good life. While Adler defines the three main objectives of education as (1) preparation for earning a living, (2) learning to be a good citizen of the republic, and (3) leading a morally good life, it is clear that he thinks the latter two purposes take precedence over the first because they lead to human happiness. Since learning to be a good citizen and

learning how to lead a morally good life (and in fact actually doing so) are attainable through reading the classics, that mode of study should be primary and universal.

The Paideia Program (from *paidos*, Greek for "raising a child") was based on an educational reform proposal from Adler and a group of like-minded scientists, educators, and business leaders intended to promote the reading and study of the great books. The program was based on the following tenets:

- All children are educable.
- Education is a lifelong activity.
- The primary cause of learning is the activity of the child's mind, which is assisted by the teacher.
- Multiple types of learning and teaching, including coaching and extended discussion, should augment lecturing.
- Preparing to earn a living is not the primary objective of education.

In many ways, the program was a "back to basics" reform proposal, with reading, writing, and arithmetic at the heart of it. It was also a self-consciously democratic and egalitarian proposal. In the words of Adler (1998), "equality of educational opportunity" is not

> taking all the children into the public schools for the same number of hours, days, and years. If once there they are divided into the sheep and the goats, into those destined solely for toil and those destined for economic and political leadership and for a quality of life to which all should have access, then the democratic purpose has been undermined by an inadequate system of public schooling. (p. 5)

Given his argument for a universal great books education, it is somewhat ironic that Adler's name and the Paideia Program have been associated with elitist approaches to education. There are three apparent reasons for the recurrent charges of elitism. The first is that great books curricula have usually taken root and flourished only at wealthy, private institutions such as Columbia, The University of Chicago, and Stanford—which abandoned its required freshman great books curriculum in the late 1980s but maintains an optional program (known as SLE, for "structured liberal education"), as does Yale ("directed studies")—or at renowned, equally wealthy, liberal arts colleges. (Exceptions that arguably prove the rule are honors programs at state universities, like the Honors College at the University of Houston, that require a Paideia-like curriculum for all majors.)

The second source of suspicion of elitism derives from a constellation of practical and populist notions about the vocational purpose of education, some of the more sophisticated of which derive from Adler's old foe John Dewey. Adler does not help his cause with such critics when he argues that the ancients regarded the training for particular jobs as the training of slaves. In Adler's view, the ancients, always his authority on matters of education, saw the pursuit of happiness as the universal human vocation and the primary, if not the sole, purpose of education.

Finally, programs inspired or supported by Adler have faced charges of bias and elitism. In 1986, these charges flared during debates at Stanford University, when students and faculty challenged a freshman requirement and its "core list" of 15 works, from Homer and the Hebrew Bible to Marx, Darwin, and Freud. The controversy culminated in 1989 with Stanford replacing "Western Culture" with a multicultural course titled "Culture, Institutions, and Values," or CIV. More directly and personally, charges of racism and sexism hounded Adler then and continue to this day—for his sometimes strident opposition to the inclusion of works by non-Western and non-European writers as well as works by women and persons of color and for his unwavering advocacy of the so-called canon consisting almost exclusively of "dead White males." Champions of multiculturalism at Stanford and elsewhere included Black student organizations, feminist groups, and others on the cultural left who argued that a curriculum like Adler's could not be relevant to the contemporary world in which students lived. The lack of "balance" in the curriculum was proof that there must be a bias beneath the egalitarian surface of the Paideia Program. Adler countered that great books, as opposed to good books, are not relevant for one moment or locale but for all time and that they provide an essential grounding for everyone—a common culture necessary for a functional democracy.

With multicultural critics of content on one side and populist critics of purpose on another, Adler's great books curriculum faced opposition on both the left and the right. During the 1980s and 1990s, the reputation of Adler's unifying and democratizing intentions were tarnished when critics lumped him with E. D. Hirsch, who helped fan the culture wars with his call for a "national culture," and Allan Bloom and William Bennett, both of whom Adler

considered elitist. More recently, Nel Noddings developed a nuanced alternative to Adler's program, which she calls a "Whitmanesque" curriculum, for poet Walt Whitman. Adler's insistence on a one-track system of education ignores real differences in talent and interest, Noddings claims, thus alienating and humiliating students who are not engaged by a Paideia-like program of study. She advocates a broader, less bookish, understanding of intellectual work, one that includes those who cook and those who repair as well as those who speak and write. Summarizing, then, critics of Adler object to the impractical, nonvocational nature of his program, the rigidity of its application to all children, and the preponderance of Western, White, and male writers in his great books canon.

Respecting the last and best known of these objections, great books programs are now often modified to include "alternative voices": works by women, persons of color, and non-Western/non-European authors. At almost every institution influenced by Adler, his 54 great books and the 102 great ideas he indexed in the *Synopticon* have been expanded and modified, and educators are generally less sanguine about the universality and sufficiency of their approach. Yet Adler's central insight still underlies much of what is identified as "core" or general education in schools, colleges, and universities. If they cannot agree on a list of titles, many, if not most, educators do believe in classic, universally valuable books and perennial ideas that are relevant to human problems in all times and situations. The implicit, if not explicit, assumption is that some ideas endure and broadly influence individuals and societies, and some books, let us call them "great," reward and sustain when read with attention and care.

Adolescent Development

Adolescence typically refers to the period of life between the onset of puberty and adulthood. G. Stanley Hall (1844–1924) is usually credited with initiating scholarly interest in this developmental stage, which he viewed as a period of storm and stress (*Sturm und Drang*). For many theorists, adolescence represents a critical phase of human development as it does cover a period of demonstrable change, and many individuals have claimed that key aspects of their own thought and attitudes have taken root during adolescence. However, as Allan Wigfield, James Byrnes, and Jacquelynne Eccles (2006) have stressed, "Adolescence is very much a cultural phenomenon and the experiences adolescents have vary greatly across different cultures" (p. 88). This entry focuses on contributions to four main areas of adolescent development as studied in North American and Western contexts: (1) physical changes, (2) cognitive development, (3) social development, and (4) environmental changes that occur during adolescence.

Physical Changes

Puberty is the developmental process that is, perhaps, most closely associated with adolescence. Adolescence is often thought of as a period of storm and stress. Although these years are marked by substantial biological change, most scholarly work has determined that this "raging-hormones" view of adolescence is overstated. A key issue regarding puberty with respect to education is the timing of its onset. On average, the onset of puberty is about 18 months earlier for girls (usually starting around the age of 10 to 11 and lasting until they are 15 to 17)

than for boys (who usually begin puberty at about the age of 11 to 12 and complete it by the age of 16 to 17, on average).

The prevailing school of thought has been that better outcomes result for girls who hit puberty later and for boys who hit puberty earlier. As boys and girls hit their growth spurts, early-developing boys may stand out as suddenly looking more like the cultural ideal of the strong, tall, broad-shouldered man. They may also reap advantages from their size in athletic domains. In contrast, girls who hit puberty early may be embarrassed by their larger size (which runs counter to the cultural ideal). Furthermore, their physical development may open doorways to older peer groups and expose them to a riskier array of activities.

However, recent research has found exceptions to these trends. One emerging line of thinking is that while the physical changes may cause minor problems for some students, the real issue for educators arises when students face multiple transitions simultaneously. For example, a girl who begins puberty ahead of most of her peers as she transitions to a new middle school with new teachers and new peers may face multiple risk factors.

Cognitive Development

Within the domain of cognitive development, Jean Piaget's views have been particularly influential. Although less explicitly developmental, information processing views and Lev Vygotsky's social learning approach have offered prominent and competing views of how cognitive development may progress during adolescence.

Jean Piaget

In Piaget's view, cognitive development takes place through four distinct phases. He described (1) from birth through age 2 as the *sensorimotor period*, (2) from 2 to 7 years of age as the *preoperational period*, (3) from 7 through 11 years of age as *concrete operations*, and (4) from 11 years into adulthood as the *formal operations* period. For adolescents, what makes formal operations a qualitatively distinct way of thinking is the capacity for abstract thought. Specifically, in this view, what emerges during adolescence is a capacity (a) to think systematically (e.g., by isolating variables); (b) to entertain hypothetical presuppositions, counterfactuals, or alternatives; and (c) to make logical deductions. For example, a problem such as the following would require formal operations: Dennis is taller than Denise but shorter than Phillip. Phillip is shorter than Phyllis. Who is taller, Dennis or Phyllis?

Critique of Piaget's theory—specifically his work regarding formal operations—has come from three main sources. One line of questioning has raised the issue of whether changes in task performance that occur for youth transitioning into adolescence can actually be attributed to changes in logical thinking. A second line asks whether these changes really occur in stagelike fashion. Finally, questions about the universality of this stage have been raised—in other words, do all (or only some) late adolescents achieve formal operations and do they do so for all domains? Much of the evidence marshaled in support of these critiques has shown that, with proper training, much younger students can perform tasks requiring formal operations. Conversely, for novel domains, many late adolescents fail to successfully complete these types of tasks.

Information Processing

According to the information processing model, learners are like computers. Key functions of learners (and computers) are to receive and encode information from the environment, which must then be stored, organized, and remembered (as files must be saved). To use the information, people must recall it from memory (in the same way that old files may be reopened). These processes are controlled by executive functions—that is, *metacognitive skills*, such as attention regulation and rehearsal of information, and *elaboration* processes in which connections are made between pieces of information.

For the most part, scholars who adopt this general view of cognitive development see adolescence as a continuation of normal development. In other words, for adolescents, cognitive development occurs in much the same way as it does for younger students and adults. These scholars tend to find that development occurs differently in different domains—adolescents with substantial knowledge or experience in a domain may be able to perform much more sophisticated cognitive tasks than adolescents with little prior knowledge in the domain.

Lev Vygotsky

Although Vygotsky's theory of cognitive development does not focus on adolescents explicitly, several key ideas are regarded as especially important during this developmental phase. Vygotsky posited

that a primary learning pathway occurs between people—specifically between relative novices within a domain (e.g., children) and more experienced learners (e.g., parents or teachers). By working with more advanced others within a given domain, a relative novice can progress within a *zone of proximal development*. This zone represents the gap between what the learner can do alone and what he or she can do with assistance from a more experienced partner. In ongoing learning relationships, the more experienced partner provides *scaffolding* to help the novice with challenging tasks. As proficiency develops on those tasks, the scaffolding is removed so that the novice performs the task with increasing amounts of independence. During adolescence, improved metacognitive capacities allow youths to better able to plan, monitor, and evaluate their learning. Thus, it becomes increasingly viable for adolescents to scaffold one another's learning and help advance each other's zone of proximal development rather than relying on adults.

Synthesis

Although burgeoning empirical evidence casts doubt on certain aspects of Piaget's theory, adolescents may appear to take a leap forward in their cognitive development because the combination of their increasing cognitive capacity (in terms of memory and abstract thinking) and executive functioning capabilities allows them to devote greater cognitive resources to problem solving in domains where they have background knowledge. In domains where adolescents are less experienced and less knowledgeable, they may require more scaffolding from more experienced others. Findings from neuroscientific examinations of cognitive development provide some support for this possibility—adolescents experience important changes in brain structure and neurotransmitter levels that help enhance their executive functioning.

Social Development

During adolescence, people begin to develop their own identities and work out who they are in relation to others. The key researchers in this area include Erik Erikson, James Marcia, and David Elkind.

Identity Development: Erik Erikson and James Marcia

One of the hallmark tasks of adolescence is that of identity development. According to Erikson's stage theory, a core issue for adolescents to work out is that of *identity versus role confusion*. In other words, adolescents should strive to begin to define themselves in terms of their values, vocational interests, political and religious views, and so on through the exploration of the "Who am I?" question.

Marcia extended Erikson's theory by positing four outcomes to explorations of this question. An adolescent in *foreclosure* status has insufficiently explored this question and, instead, usually adopts the views of parents or friends without questioning them in a meaningful way. Adolescents experiencing *identity diffusion*, by contrast, have begun exploring the "Who am I?" question; they simply have not reached many conclusions. *Moratorium* describes the status of adolescents who are deeply engaged in the exploration of their identity, though whatever conclusions they may have reached at this point are likely tentative. Adolescents in *identity achievement* have typically undergone more thorough explorations of who they are and have made decisions about several aspects of their identity.

Social Cognition: David Elkind

Perhaps because of the view that they are undergoing a period of self-exploration, adolescents have garnered a reputation for egocentrism. Elkind proposed two metaphors to describe the ways in which adolescents become particularly susceptible to egocentric thought. Through the creation of an *imaginary audience*, adolescents think that others are thinking about and paying more attention to them than is actually occurring in reality. A particular consequence of this belief is the increased concern over appearance. By developing a *personal fable*, adolescents begin seeing themselves as special and unique. Believing too strongly in a personal fable can cause problems for an adolescent if it leads to feelings of invincibility or to feeling that nobody else can relate to him or her.

Although intuitively compelling, these metaphors—and the generalization that there is a peak in egocentrism during adolescence—have been questioned on several fronts. Most problematic for Elkind's theory is the view that adolescence is the time when youth develop the capacity to take the perspective of others in a sophisticated way.

Relationships

Two trends mark the progression of relationships during adolescence. First, adolescents tend to seek increased amounts of autonomy from their parents

during this phase. Second, they typically invest more time and emotional energy in their peer friendships. In other words, as adolescence progresses, individuals seek more of their relational and belongingness needs through their friends and often rely less and less on their parents for intimacy needs and emotional support. Although the existence of these trends is widely agreed on, a contentious debate has emerged surrounding Judith Rich Harris's assertion that peers are a vastly more influential factor than parents with regard to youth outcomes. To the extent that her contention is correct, there are dramatic implications for parenting, schooling, and youth development more broadly.

Synthesis

In exploring their own identities, two tools might become particularly important for adolescents—(1) their relationships with others and (2) their capacity to think about themselves with respect to those relationships. A particularly useful approach to exploring the "Who am I?" question is through ascertaining what one values. Youth can explore different values by "trying on" different sets of beliefs and behaviors in the context of different peer groups or cliques. Through these types of interactions and concurrent discussions with friends, students can more easily explore different identities than they can with their parents (who presumably lack the diversity of identities or points of view a large peer group can provide). Thus, parents may perceive their adolescent children as egocentric in their behavior; however, their children may simply be more motivated to take the perspective of their peers than their parents. To facilitate the exploration of their identities, they may be particularly motivated to understand what their peers think about themselves.

Changes in Schooling and School Contexts

As adolescents are experiencing these physical, cognitive, and social changes, they are also frequently faced with a dramatic change in context. As students transition from elementary school to secondary school, they frequently confront a new approach to schooling in a starkly different context. Secondary school students tend to move between different teachers for different subjects rather than having a single teacher instruct them in most areas; they are introduced to a new, larger peer group; and the nature of the instruction in their classes often differs from elementary school.

This change in environment is associated with a significant drop across a constellation of motivation-related outcomes (e.g., adolescents' sense of confidence, levels of intrinsic interest, positive feelings toward school, etc.). In addition, academic achievement typically suffers. Although these drops in achievement and motivation are most severe at the transition from elementary to secondary school, declines tend to continue as students advance through the grades.

Stage–Environment Fit

A prominent theory that has been introduced to explain how adolescents cope with these changes and transitions is that of the stage–environment fit (attributed to Eccles). According to this view, part of the reason that adolescents are at risk for negative consequences is that they experience a mismatch between their developmental needs and the opportunities that they receive in their secondary school environments. For example, these early adolescents are increasingly seeking autonomy, may need increased support from teachers to the extent that they are relying less on their parents, and require novel cognitive challenges. Yet their school environments frequently provide them with more controlling teachers and classroom contexts, teachers who feel less competent and whom they only see for short amounts of time each day, and coursework that may be less complex than the tasks they received in elementary school.

An important note is that this theory rose to prominence at a time when most students transitioned from elementary schools to junior highs (usually containing seventh through ninth grades). At present, middle schools (usually containing sixth through eighth grades and attempting to provide a more personalized experience) and primary schools appear more prominent. Thus, the empirical support for this theory needs to be revisited in light of these changes.

Advance Organizers

In the psychological study of learning, the 1960s marked a shift from behavioral models grounded in stimulus–response associations toward cognitive models derived from the notion that organization and structure were key features of human memory and learning (Mayer & Wittrock, 1996). Behaviorists emphasized the reinforcement of specific, small "steps" that cumulated to form large, complex achievements. Learning hierarchies as described by Gagne (1965) divided large tasks into subtasks, introducing the concept of structural strategies; subtasks were generally larger than stimulus–response associations, and considerable attention was given to the division into subtasks. At about the same time, David Ausubel introduced the concept of *advance organizers* (AO; Ausubel, 1960, 1968, 2000; Ausubel & Fitzgerald, 1961; Ausubel & Youssef, 1963). Ausubel focused on *meaningful verbal learning*, the comprehension of meaningful passages of 2,000+ words—material that was much too large to handle as small steps and much more complex than hierarchies. To assist readers' comprehension, Ausubel proposed including a brief preview—a few sentences or a paragraph—that captured the essential elements in the target material and relations among them, thus providing a structural framework that would facilitate learning, promote long-term retention, and provide a basis for transfer. Initial findings by Ausubel and others found positive effects from the AO strategy, but Barnes and Clausen (1975) wrote a lengthy review concluding that "advance organizers, as presently constructed, do not facilitate learning" (p. 651). Mayer (1979) responded by pointing out flaws in the Barnes-Clausen review and reporting a series of nine studies that clarified the conditions under which AOs were effective. This entry details the types of AOs that can be used with students and discusses how and when instructional designers might consider using them.

During the half century since Ausubel's 1960 article, structural learning has become a dominant paradigm in educational psychology. While research on AOs has diminished, Ausubel's ideas have persisted under titles such as *schemata* (Anderson, Spiro, & Montague, 1977), *semantic organizers* (Dinnell & Glover, 1985), and *text structure* (Chambliss & Calfee, 1998). The AO story illustrates how an apparently simple idea can set in motion a cavalcade of activities, extending and clarifying the original notions and advancing the field as a whole—even though the original labels and names may grow faint with time. The next section illustrates the AO concept and describes advances in comprehension springing from this concept that have emerged from subsequent critiques and debates.

The passage on *kinds of muscle cells* in Figure 1 will be used to illustrate the AO concept. The materials, shown in the left-hand panel, include a section from a high school biology text and a figure. This passage, though shorter than those in AO studies (200 words vs. 3,000 words), is both complex and difficult and serves to demonstrate the basic principles of the AO strategy.

How might a learner study this material in preparation for an examination? How might an instructional designer assist the learner in this task? One approach is based on rote memory, which might work for a small amount of material. The passage consists of about 500 separate propositions, each of which would have to be committed to memory through practice. The student also has to learn new and unfamiliar vocabulary items, which are listed for study: *contract*, *relax*, and *tendon*, along with *voluntary*, *smooth*, and *cardiac muscle* (*lactic acid* might be added to the list). Even for a short passage,

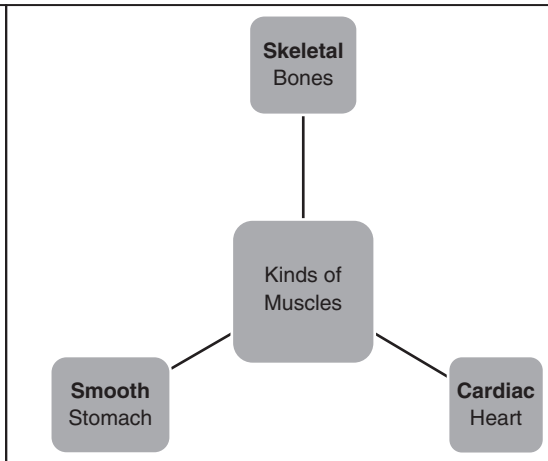
Three kinds of muscle cells make up the more than 600 muscles in your body. Each kind performs a different job, and as you see, each appears different through a microscope. Despite the differences, all muscle cells contract, making themselves longer. When not contracting, they relax, returning to their original length. The simple motion of contraction causes every movement in your body

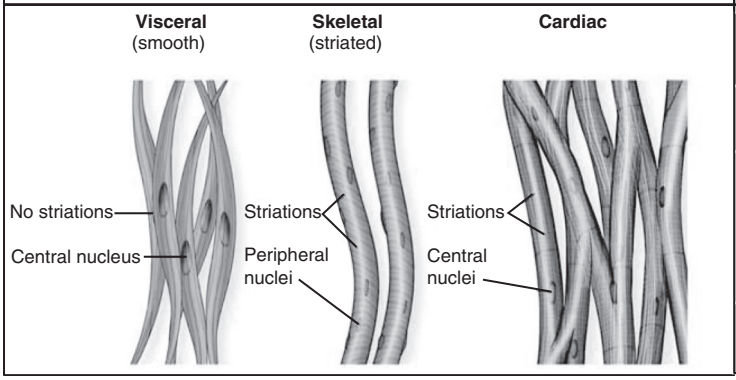
Skeletal muscles make your skeleton move. You use these muscles when you run, lift, or write. Skeletal muscles are voluntary, because you can choose when to contract them.

Bundles of **smooth muscle** are in your internal organs, like your stomach. Smooth muscles are involuntary, because you do not decide when to contract them. They perform slow, steady contractions. They help move food through your digestive tract and control blood pressure.

Your heart is made up of **cardiac muscles.** They contract very strongly and regularly, and rarely tire. Each cardiac cell has its own built-in rhythm. Cardiac muscles, like smooth muscles, are involuntary.

After vigorous exercise, muscles tire and ache due to the build-up of lactic acid, which is a by-product of muscle activity.





Kind of Muscle	Location	Use	Endurance	Contraction
Skeletal	Skeleton, bones	Move body parts	Tires quickly	Voluntary
Smooth	Internal organs, stomach, diaphragm, blood vessels	Digestion, breathing, blood flow	Long lasting	Involuntary
Cardiac	Heart	Pump blood	Steady, never stops	Rhythmic

Figure 1 Advance Organizer Options for Passage on Types of Muscles: Semantic Web (Upper Right) and Matrix (Lower Right)

Source: Text of figure adapted from Barnard, Stendler, Spock, and Edwards (1962).

rote memorization requires a lot of "small steps" to be stored in the memory.

In a learning hierarchy approach, the designer creates an outline of the material to be learned, starting with outcomes and then identifying necessary prerequisites. The designer would first introduce the prerequisites and then build on these to lead the learner through the passage. For example, the student might first be taught definitions for critical vocabulary, then taken through the three sketches, after which each of the paragraphs would be dissected in turn, and finally the pieces would be put back together. The steps are larger than for rote memory, but the learning process is still quite linear.

Structural approaches to comprehension like the AO model emphasize the "big picture." The reader, like a biologist, looks first for major skeletal elements that make up the body and then works out the detailed connections. What might provide the skeleton for *muscles*? We should assume that the designer/writer of *muscles* had a big picture in mind, and the first line offers a clue: *kinds of muscle cells*. The first sentence expands the title (*three kinds*), and the second sentence even further so (*each kind performs a different job . . . each appears different through a microscope*). The passage does not highlight the function of these two sentences; the reader must seek out elements like these that can serve as building blocks (or bones) for organizing the material. The human mind is naturally inclined to organize repeated experiences—to form *schemata* that extract the essential elements from everyday activities like trips to the grocery store. Reading comprehension is a complex and demanding activity, and a primary outcome of comprehension instruction occurs when the reader has learned to search for candidate schemata when encountering an unfamiliar passage and to build a new one if necessary. With this model in mind, the AO concept was proposed as a scaffolding strategy to support beginning comprehenders in dealing with difficult materials, by providing a schema in advance. The topic *muscles*

provides several opportunities for illustrating these issues. Ausubel proposed that either a summary (a synopsis of the material with low-level propositions deleted, e.g., *lactic acid*, is not connected to *kinds*) or a classical outline might serve as an AO for this passage. The textbook actually included a preview paragraph similar to the AOs used by Ausubel in the 1960s:

> Make a mental list of all the ways that you used your muscles today. You might include running, walking, and writing. But did you add pumping blood through your heart or churning the food in your stomach? Muscles do all of these things and more.

The preview identifies the key topic, *muscles*; reminds the learner about something he or she already knows; and then lists surprising ideas like pumping blood and churning food. It does not, however, offer any hints about the primary structural feature—three kinds of muscles serve three different functions—that emerged from our reconstruction of the text.

The early AO studies relied on text material (summaries and outlines), but graphic organizers (Chambliss & Calfee, 1998) offer several advantages, and in the digital age, they have become an integral part of virtually every "office suite." For example, *muscles* might be handled as a *semantic web:* a central core with three spokes, like the one to the upper right in Figure 1. A *matrix* like that to the lower right requires more work, but it provides greater structural support. The *muscles* matrix lays out the *three types* in the first column, after which *different features* are added, and then the various cells are filled in. One advantage of the matrix structure over a semantic web is that it focuses attention on the differential features that are the essential idea in the passage. The cells also provide pointers to specific details that the reader needs to look for, details that may not necessarily be in the passage but that the reader might know from prior experience.

In what ways might an instructional designer show a student how to use a matrix as an organizer? A similar question might be raised for an advance "paragraph," but the graphic layout makes it easier to formulate this question. One approach is to present a bare-bones "three-kinds" matrix; the first column is filled in, and everything else is blank. The reader has to generate column entries and fill in the cells. Or the designer might provide the column headings, since these are presently hidden in the text, to guide the reader in moving through the text. Finally, an experienced student would be expected to create a matrix when confronted with clues like those that are hidden in *muscles*; the ultimate value of the AO approach occurs when the student has internalized the strategy.

This example also raises the question of "when" to use an AO—before, during, or after reading. If presented in advance, the matrix provides a concrete template or schema for guiding comprehension; the reader is relieved of a major comprehension challenge, freeing memory to work on passage details. If available during reading, the matrix helps the reader keep track of the messages in the material, while also promoting active engagement if columns or cells are empty. If given to the reader after learning, the matrix can support retrieval of the material, which might be useful for the assessment of transfer—for example, "Based on what you learned about muscles, how would you predict nerve control for each kind of muscle cell?"

Figure 1 illustrates theoretical and practical investigations that have sprung from Ausubel's introduction of the AO concept. The most extensive developments have centered on extensions of assimilation (the connection of new learning to previous memories) and accommodation (changes in previous memories produced by new learning; Piaget & Inhelder, 2000). Mayer (1977, 1979) produced the most comprehensive reports along these lines. One series of studies (Mayer, 1979, pp. 373ff) explored AO impact on *reception* (encoding of information into working memory), *transformation* ("anchoring" of information during transfer from working to long-term memory), *assimilation* (integration with existing information), and *retrieval* (access to material at various points and in different situations after learning). The results showed that AO effects could be quite substantial (or not) depending on the nature of the target material, the knowledge and experience that learners brought to the situation, and the measures used to assess outcomes. For example, AO effects were generally small when recall was tested immediately with a recognition test, but they were much more substantial when tested after a substantial delay on an essay test. Learners who knew more about the topic benefited less from AO support than those who brought less to the task. For each of these findings, Mayer's conclusions were grounded in empirical studies of the underlying cognitive processes.

The idea of offering a road map for the reader about to engage with a long and difficult text might seem rather commonsensical, but the progression

of thinking that emerged from investigations of this notion illustrates how thoughtful scholarship and empirical study can inform and advance common sense. How should an organizer be constructed? How should the reader be guided in using an organizer? When should an organizer be presented—before (in advance), during (for ongoing support), or after (to review) engaging in the target material? These are but a few of the issues that arose from AO research. Perhaps the most significant contributions emerged from explorations of "how" and "why." What cognitive processes are at work when a reader employs an organizer of some sort, and why can an instructional designer most effectively employ an organizer in a particular setting?

The AO episode also illustrates the potential of efforts at bridging theory and practice, and in wrestling with a difficult problem to seek deeper understanding of the issues. Story (1998) asked, "What do instructional designers need to know about advance articles?" and rightly concluded that the answer depends on what is to be learned, who are the learners, and what are the outcomes. Story was concerned about the lack of detailed comparative studies, but the AO history suggests that designers must take an engineering approach rather than search for "pure principles." There is no general answer to the question of how to construct a suspension bridge like the Golden Gate. It depends on a variety of factors, along with principles from physical mechanics. In designing effective supports for learning new and complex ideas, instructors and designers cannot point to "one right answer," but they can draw on rich literatures such as AO research to point toward factors that matter, and to theoretical models available from cognitive learning theory, as foundation stones for designing and evaluating the effectiveness of different solutions.

Aesthetic Education

Although debates about beauty and judgments of personal taste date back thousands of years, the word *aesthetics* and the conception of aesthetics as a philosophical branch of axiology are relatively recent inventions that belong to the mid-18th-century German Enlightenment. Originally intended as a philosophy of reasoning through felt sensory experience

as evoked through poetry, *aesthetics* was quickly appropriated into widespread popular use as an umbrella term to embrace all discussions concerning the judgments of beauty and art. In these early formulations, beauty corresponded to truth; thus, beauty said truthful things about the world. Art was an empirical expression of beauty. This entry traces the evolution of the original German concept of aesthetic education and then examines three different contemporary theories: (1) the essentialist, (2) the cultural, and (3) the cognitive. Finally, the Lincoln Center Institute in New York provides a curricular example of integrating these aesthetic education theories into practice.

Aesthetic Education as a Curricular Concern

In 1795, Friedrich Schiller, writing at a time of high exhilaration and anxiety over the recent American and French revolutions, posited aesthetic education as essential to the development of individuals who could think for themselves. According to Schiller, only aesthetic education could train a new generation of citizens who were capable of forming their own judgments. In the presence of beauty, individuals would experience and come to know truth, without being told by authorities what to do. Early-19th-century advocates for public schooling in both Germany and the United States rapidly adopted Schiller's conception of aesthetic education as a tool for creating a competent democratic citizenry.

Perhaps the first practitioner to move Schiller's theory into a school curriculum was the Swiss educator Johann Pestalozzi. Working with orphans and disadvantaged children, Pestalozzi saw aesthetic education as a means of enticing children into learning. Eventually, Pestalozzi's curriculum became the foundation for the German drawing method adapted by the emergent Prussian system for public education. In turn, American transcendentalists Horace Mann and Mary Peabody traveled to Germany to observe this curriculum in practice. They brought it to the United States and the new public school systems in America.

Separately, Pestalozzi's student Friedrich Froebel advocated another path of aesthetics as experiential sensory education: the kindergarten. Mary Peabody's sister, Elizabeth Peabody, was instrumental in bringing this innovation to the United States. In yet another track, in the 20th century, Rudolf Steiner would build on Pestalozzi's curriculum to construct Waldorf education.

While theses evolutions of aesthetic education into schooling may appear to form a tidy narrative, it is hardly so. The 20th century actively decoupled the concept of beauty from truth, as well as beauty from art. Arthur Danto famously claimed that by 1964 we had reached the end of art. For aesthetics to be a part of philosophy, there had to be objects that belonged to the domain and others that could be logically excluded. If anything could be art, Danto claimed, the philosophical project of aesthetics was over. Today, the degradation of the term *aesthetics* is readily apparent. For example, *an aesthetician* can refer to both a university professor of philosophy and a beauty parlor nail specialist. A term with such chameleon qualities is difficult to use in scholarly discourse.

Three Views of Aesthetics and Education

Nevertheless, the philosopher Richard Shusterman (2006) offers three useful categories for conceptualizing the continuing role of aesthetics in education. First and foremost, aesthetics refers to essentialist universal judgments of beauty. This is commonly associated with the philosophy of Immanuel Kant. In this conception, there is enduring, universal knowledge that cuts across time and cultures. Any educated person needs to know this foundational material. The advocates for this position argue that all students should, at minimum, be able to identify exemplar works by major artistic figures such as William Shakespeare, Leonardo da Vinci, or Ludwig van Beethoven. Moreover, they should also be able to obtain aesthetic satisfaction (i.e., pleasure and delight) from these works. The curricular theorist Harry Broudy (1972) referred to this as "enlightened cherishing." Today, the *Journal of Aesthetic Education* continues Broudy's legacy.

Shusterman's second philosophical category is cultural. The philosophy of Georg Wilhelm Friedrich Hegel is readily associated with this view. In this conception, there are no universal truths, but it is valuable to study the contributions of different cultures. For example, the study of West African kente cloth (a foundational and perennial aesthetic tradition within Ashanti culture) provides a means for individuals who are outsiders to have an empathetic understanding of Ashanti culture. Aesthetic education would engage students in studying how cultural values are inscribed in an object. Studying distinctive ways of inscribing opens students to understanding the possibilities of the human imagination. Maxine

Greene (2001) is an important contemporary proponent of this view, as aesthetic education opens inquiry into the potential for humans to communicate within and outside of language. Here, aesthetic education easily steps into multimodal literacy education by allowing creative work from outsider youth subcultures such as graphic novels, zines, and comic jamming a place in the literacy classroom.

Shusterman's third category is the cognitive. As stated earlier, the original philosophy project was the study of rational thinking through the senses. Pestalozzi claimed that the mind was shaped through drawing. Early German writings in aesthetic education claimed that students experienced a special form of being in relationship. At first, this German concept could not be adequately translated into English, so by the early 20th century, a new word had been created: *empathy*. Thus, empathy is a content goal for learning within aesthetic education.

Here, empathy is more than simply understanding another culture (as in the kente cloth example). Empathy is also a capacity to understand one's self—the sensate body—in relationship to the world. John Dewey's *Art as Experience* (1934/1989) explores how sense serves as a provocateur to symbolic thinking. Simultaneously with Dewey's American-based inquiry into prelinguistic thinking, the emerging German philosophies of hermeneutics and phenomenology explore similar issues. George Lakoff and Mark Johnson (1999) are contemporary advocates for such embodied philosophy. In a pragmatic approach to actual classroom practice, award-winning children's author Molly Bang's *Picture This: How Pictures Work* (2000) offers examples of how visual images convey narrative, without the use of words, through the relationship of visual qualities. Bang demonstrates how pictures convey complex intuitions before students may have the words to articulate understandings.

Postmodern aesthetic education also falls into this third category. Postcolonial scholar Gayatri Chakravorty Spivak (2012) evokes Schiller's original project as a practice of resistance to institutional authority. She frames aesthetic education as disciplined subversion to the tyranny of language, in order that autonomous individuals can emerge in a time of relentless global standardization.

Curricular Applications of Aesthetic Education

Institutions that foster curricula in aesthetic education can intentionally or unintentionally blend all three of Shusterman's categories. The Lincoln Center Institute, the educational wing of the Lincoln Center for the Performing Arts in New York City, provides an example. Closely aligned with the work of Greene, Lincoln Center Institute first seeks to build audiences for the expensive cultural productions mounted at Lincoln Center. The institute fosters an appreciation of enduring excellence, Shusterman's first category of aesthetics. Second, the institute works with multiple art forms that reflect the diverse populations of New York City and sends teaching artists into classrooms to work with children in the children's own cultural contexts. This builds empathetic relationships, Shusterman's second strand. Third, Greene's philosophy champions imagination launched by deeply felt somatic experience, Shusterman's third strand of aesthetics. Thus, one could argue that the Lincoln Center Institute offers a rich integrative approach to aesthetic education. However, whether a curriculum is integrative or merely confused requires close attention to the alignment of objectives, activities, and assessment.

Affirmative Action

The phrase *affirmative action* entered policy discourse in the United States in 1961, with President John F. Kennedy's Executive Order 10925, which called for all federal agencies to take affirmative action to avoid discrimination in their hiring practices. However, the phrase *affirmative action* was not defined. The term was used again in President Lyndon B. Johnson's 1965 Executive Order 11246, which revised Executive Order 10925, but it still was not officially defined. Three years later, the Department of Labor, responsible for enforcing the policy, characterized affirmative action as a program emphasizing increased opportunities for underrepresented groups through expanded applicant pools and active recruiting and outreach strategies. Since then, debates over the merits of affirmative action policies and programs have endured, underscoring differences in ethical and political values.

Although specific programs may differ from one another, affirmative action is most often defined as a policy that aims to take an applicant's race, ethnicity, and gender into account in selection decisions. In the United States, this means that if an applicant is African American, Latino, Asian American, Native American, and/or female, this fact is taken as one qualifying factor among many considered in admissions or hiring processes. The range of affirmative action programs is broad, from federal contracts to employment and promotion, to college and university admissions. On the basis of the affirmative action policies in Executive Order 11246 and Title VI of the Civil Rights Act of 1964, which specified that discrimination by race, color, religion, sex, or national origin was prohibited by agencies receiving federal funding, many businesses, public agencies, and institutions of higher education began to revise their admissions and hiring policies so that a broader pool of people could have increased educational and employment opportunities.

The controversy over affirmative action has resulted in numerous important court cases that have shaped the contours of the policy. Those cases include most prominently *Regents of the University of California v. Bakke* (1978), *Gratz v. Bollinger* (2003), *Grutter v. Bollinger* (2003), *Parents Involved in Community Schools v. Seattle School District No. 1*, *Meredith v. Jefferson County Board of Education* (the last two cases were combined by the U.S. Supreme Court as *Parents Involved in Community Schools v. Seattle School District No. 1, et al.,* 127 S. Ct. 2738 [2007], known as *PICS*, 2007), and *Fisher v. University of Texas* (2013). In a series of cases since *Bakke*, the Court has set limits on the use of affirmative action policies in education and employment. It has narrowed the use of race-conscious affirmative action in education, at both the higher education level and the K–12 level, but the practice remains legal and viable. Quotas are rarely if ever used, based on the *Bakke* ruling against quotas and set-aside places at universities. *Gratz* reinforced the impermissibility for numeric set-asides in university admissions, and *Grutter* upheld the constitutionality of affirmative action plans that are narrowly tailored to serve the compelling government interest of diversity. In the *PICS* case, the Supreme Court ruled that voluntary racial integration plans in place in school districts in Seattle and Louisville were not narrowly tailored and, thus, unconstitutional. However, it did not overturn *Grutter*, and it supported the idea that diversity is a compelling interest in both higher education and K–12. In its June 24, 2013, ruling in *Fisher*, the Court ruled 7:1 that institutions of higher education are permitted to consider race or ethnicity as one factor in the admissions process. In addition, the Court declined to rule on the specific case and instead remanded it back to the lower courts. What this means for affirmative action policy in 2013 is that the Court declined to strike down the *Grutter* precedent through *Fisher.* It also means that institutions of higher education practicing affirmative action in their admissions would be prudent to design those policies in accord with the *Grutter* decision's mandate for flexible and individualized applicant review.

The affirmative action debate is characterized by a set of prominent rationales in favor of its use, on one side, and a set of criticisms of it, on the other. These are described in the next sections.

Prominent Justifications for Affirmative Action

As Moses (2010) has described, common justifications for affirmative action have typically fallen under four categories: (1) remediation, (2) economics, (3) diversity, and (4) social justice.

Under remediation, affirmative action compensates for past discrimination. The remedial rationale is a moral justification aimed at righting past wrongs and emphasizing compensatory, corrective action to rectify unfair treatment by race, ethnicity, and gender. Remediation was once the most prominent rationale used in the United States, until the courts showed it to be viable only in some specific cases of provable past discrimination, and the U.S. Supreme Court found it to be a less compelling rationale than arguments based on diversity.

Economic rationales highlight affirmative action as helping disadvantaged people contribute to economic efficiency and productivity. An instrumental rationale, the economic argument for affirmative action centers first on society's need for a greater number of disadvantaged people to be educated and to join the workforce and contribute to the economy. Second, economic efficiency requires the development of more role models for disadvantaged youth, so they will understand the importance of contributing to society and believe that they are capable of making such contributions. In this case, "contributing" signifies making economic contributions and no longer relying on welfare. Appeals to the role of affirmative action in increasing people's later economic productivity or engagement in mainstream economic affairs have not been as compelling as the diversity rationale in the United States, either in the public discourse or in the legal arena.

Under the diversity rationale, affirmative action serves to increase diversity and the educational and social benefits that flow from it. Researchers in this area have found significant educational benefits of having diverse classrooms, campuses, and work environments, specifically so that they improve research quality, learning experiences, problem-solving abilities, critical-thinking skills, and preparation for life in a multicultural society. Stemming from Justice Lewis Powell's opinion in the *Bakke* decision, affirmative action is a compelling state interest because of the educational benefits that flow from a diverse student body. Justice Powell explained that a diverse student body increases and deepens the perspectives present in classrooms and on campus, allowing for a richer learning environment. The diversity rationale became even more prominent after the 2003 *Grutter* decision. The University of Michigan defense in this case relied most heavily on the *Bakke* precedent to justify affirmative action in university admissions based on a compelling state interest to have racially and ethnically diverse institutions of higher education.

The social justice rationale focuses on racial integration, elimination of institutionalized inequalities, and equity in democratic participation. Relevant here is Young's (1990) definition of social justice as "the elimination of institutionalized domination and oppression" (p. 15). Social policies and societal institutions directly influence the presence of social justice (Arthur & Shaw, 1991). As Anderson (2002) argued, racial integration is important in providing opportunities to racial minorities and for fostering a democratic civil society. Through its role in increasing educational and social opportunities, affirmative action expands its beneficiaries' social context of choice—the context within which they make decisions about the future and participate in democratic politics.

Other scholars have made distinctions between types of justification. Anderson (2002), for one, highlighted two justificatory categories for affirmative action: (1) compensatory and (2) integrative. Under compensatory justifications, affirmative action policies provide "restitution for illegal discrimination that took place in the past" (p. 1196). This is parallel to the remediation rationale. Proponents of the integrative rationale, including Anderson herself, aim "to dismantle *current* barriers to equal opportunity for disadvantaged racial groups" (p. 1196). Anderson defined racial integration as "the full inclusion and participation as equals of citizens of all races in American institutions" (p. 1197). She explained, "The integrative model represents race-conscious affirmative action as a forward-looking remedy for segregation, rather than as a backward-looking remedy for discrimination" (p. 1197). The integrative rationale fits well under the broader rationale based on social justice.

Prominent Arguments Against Affirmative Action

According to Moses (2002), the most prominent criticisms of affirmative action center on the following: (1) reverse discrimination, (2) merit, (3) stigma, (4) social divisiveness, and (5) social class.

The first argument is that affirmative action amounts to reverse discrimination and violates key civil rights legislation such as the 14th Amendment and Title VI of the Civil Rights Act. Critics argue that when institutions take an applicant's race or ethnicity into consideration in admissions or hiring

processes, it is tantamount to discrimination against White students. Second is the notion that affirmative action degrades the merit-based standards at selective institutions, resulting in the acceptance of students or the hiring of professionals who are unqualified for the rigors of selective education or employment. Many White students believe that affirmative action policies came at the expense of their fair educational opportunities embodied in unbiased, merit-based selection. A third criticism, often movingly brought to the fore by critics of color themselves, is that students of color admitted under affirmative action policies end up feeling inferior to their White classmates. They argue that affirmative action stigmatizes students of color who end up with damaged self-confidence or feelings of self-worth, first, because they begin to doubt that their own qualifications earned them their admission, and, second, because they cannot compete with other students at selective institutions. Fourth, a claim made by opponents of affirmative action is that it ends up causing racial divisions rather than enhancing a healthy climate of diversity. These opponents worry that the social divisiveness that affirmative action policies create leads to racial conflicts between White people and people of color, often because of the resentment that White people feel. They argue that it is time to return to the ideal of color blindness, that the divisiveness of affirmative action has been endured long enough. Last, some critics of current affirmative action argue that it should shift from race-conscious to class-conscious policies, so that low-income men and women of all racial and ethnic groups would benefit. There are those on both sides of the affirmative action issue who would solve the controversy by simply replacing race and ethnicity with socioeconomic class.

In 1978, as the U.S. Supreme Court upheld the constitutionality of race-conscious affirmative action, Justice Harry Blackmun explained, "In order to get beyond racism, we must first take account of race. There is no other way. And in order to treat some persons equally, we must treat them differently" (*Bakke*, 1978). Nearly 30 years later, the Supreme Court chief justice John Roberts argued against race-conscious student assignment policies in his majority opinion in *Parents Involved in Community Schools v. Seattle School District No. 1* (2007), asserting that "[t]he way to stop discrimination on the basis of race is to stop discriminating on the basis of race." Their disagreement is at the heart of the dispute over affirmative action and is reflected in the most prominent apologies for and criticisms of the policy.

Aims, Concept of

At first sight, the concept of aims looks philosophically untroubling. One's aims are the things one hopes to achieve by one's efforts. Aims differ from other kinds of intention in that they involve the possibility of falling short. My intention to post a letter on my way to work this morning does not count as an aim because, while it can be frustrated by my forgetfulness or my not having time to make a stop, it cannot (usually) be frustrated by the difficulty of the task in hand, by my having tried but having failed to get the letter into the mailbox. To have an aim, then, is to intend to achieve by one's efforts something one's efforts may not be sufficient to achieve.

Many of the intentions of educators have this character. Bringing about learning in others is almost always a task one's efforts may not be sufficient to achieve. Accounts of what the learning educators are

trying to bring about, either in general or on particular occasions, are therefore properly described as accounts of their aims.

So far, so uncontroversial. It may seem that the only philosophical question about educational aims left to argue about is the substantive question of what those aims should be. But in fact there has been a good deal of philosophical disagreement about how and where aims should feature in educational theory. Following is a brief survey of the most prominent strands of this disagreement.

The Conceptual Thesis

An influential thesis about the aims of education is that they are implicit in the concept of education and can be made explicit by means of conceptual analysis. On this view, associated most strongly, perhaps, with the British philosopher R. S. Peters, to ask about educational aims is to ask for a more precise specification of the activity of educating. The term *education* picks out a certain form of human activity oriented toward a certain set of ends; to give a fully elaborated account of that activity and those ends is to say all that there is to say about the aims of education.

This conceptual thesis leads Peters to draw a sharp distinction between the aims of education and a person's *purposes in educating*. While to be engaged in educating at all is necessarily to be pursuing the built-in aims of education, there may be various other things a person hopes to achieve by engaging in the activity. A teacher may care deeply about children's happiness and believe that educating them improves their chances of being happy. A government's primary motive for providing state education may be to build and maintain a strong national economy. Motivations like these, argues Peters, are extrinsic reasons for educating, not aims of education.

One worry here is that Peters seems to have introduced an arbitrary constraint on the use of the word *aim*. It is natural to say, in the cases just given, that the teacher has the aim of making children happy and the government has the aim of strengthening the economy. Perhaps, then, it would be better to distinguish between *intrinsic* and *extrinsic* educational aims. Some of the things at which educators aim are necessary to the activity of educating; others are only contingently connected to the activity. But note that this apparently small amendment to the conceptual thesis significantly narrows its scope: It is now no longer a general thesis about the aims of education but a specific thesis about one type of educational aim.

Can Extrinsic and Intrinsic Aims Be Separated?

Another worry is that the distinction between aims and purposes, or between intrinsic and extrinsic aims, may not be as clear-cut as it appears. John White argues that, while the distinction works well for games like football and chess, its application to the practice of education is more problematic. Games have well-defined sets of rules and objectives: Part and parcel of what it is to play football is to have the aim of scoring goals. Education, on the other hand, is a practice whose procedures and ends are much less determinate and are often matters of controversy. Those who have attempted to derive specific principles of curriculum and pedagogy from the concept of education have invariably been accused of writing their own ideals into the concept. There remains an important distinction between intended learning, which is the direct focus of educational effort, and intended goods of other kinds (happiness, a strong economy, etc.), to which learning is a necessary or efficient means; but if *this* is the distinction we mean to mark by talk of intrinsic and extrinsic aims, it may be doubted that conceptual analysis can yield determinate aims of either type.

Predetermined Versus Context-Sensitive Aims

A second strand of disagreement about educational aims turns on whether or not they can be specified in the abstract, in advance of engagement with particular groups of learners. One need not subscribe to the conceptual thesis to think they can. White, for example, defends by normative rather than conceptual arguments a detailed general account of the virtues, skills, knowledge, and understanding at which educators should aim. But John Dewey, in *Democracy and Education* (1916), warns against any attempt to impose on educators a set of aims determined independently of the particular contexts in which they are working.

Dewey's objection to predetermined educational aims is that they are insufficiently sensitive to the needs of individual learners and the options open to individual teachers in any given context. Aims, he contends, are central to all human activities: They are the means by which agents give direction to what they are doing. But they only serve a useful purpose if they are provisional, flexible,

and organically connected to the circumstances of action. Teachers must continually devise and revise their aims in relation to the aptitudes, interests, and preconceptions of their pupils; to the physical and pedagogical resources available to them; to the unanticipated opportunities for learning that arise through classroom interaction; and to all the other contingent features of particular educational contexts. Aims predetermined by educational theorists are responsible, says Dewey, "for rendering the work of both teacher and pupil mechanical and slavish" (p. 129).

A possible response to Dewey is to question his all-or-nothing characterization of the choice between general, context-independent aims and particular, context-sensitive ones. It is plausible to hold that there is room for both. The theoretical project of prescribing aims for education, of giving a broad, normatively justified account of the range of learning educators should be trying to bring about, may be more compatible than Dewey suggests with the practical project of giving direction to classroom activity through the formation and amendment of concrete, situation-specific aims.

Product-Oriented Versus Process-Oriented Model

A third strand of disagreement is prompted by the radical thought that educators should repudiate aims altogether. To ask what learning educators should aim to bring about, it is sometimes suggested, is to buy into a product-oriented, rather than a process-oriented, model of the curriculum. It is to assume that teaching is only effective if it is directed toward the achievement of precisely specified learning objectives. But this is a serious mistake. A characteristic feature of rich and worthwhile educational experiences is that participants learn from them in different and unpredictable ways. The point of studying, say, Shakespeare's *Hamlet*, is not that everyone in the group should come to know an identical set of facts about the play but that everyone should find something in it that moves or disturbs or inspires them, that illuminates or transforms some aspect of their experience. It would be neither possible nor desirable to specify in advance, as objectives to be pursued, the multiple ways in which learners can be touched and transformed by engagement with literary texts.

While this represents a powerful critique of the sort of rational curriculum planning associated with the work of Ralph Tyler, it is less clear that it casts genuine doubt on the need for educational aims. Lawrence Stenhouse, the most prominent advocate of the "process model" of the curriculum, does not see himself as rejecting educational aims per se but as rejecting the sort of aims that can be translated into detailed, specific learning objectives. Education, he argues, is about initiating learners into modes or systems of thought that enable them to think and judge creatively and independently. Initiating a learner into a mode of thought is a different kind of aim from teaching her a simple skill or bare fact, and no doubt one whose achievement is more difficult to assess; however, it is an aim nonetheless. So while the debate between product- and process-oriented curriculum theorists is often portrayed as a dispute about whether aims are needed in educational theory, it is perhaps better understood as a dispute about what the aims of education should be.

Alienation

The modern meaning and usage of the term *alienation* refer to becoming separated or estranged from something or oneself, and come from various philosophical, religious, and theoretical traditions. This entry will concentrate on the Hegelian and Western Marxist theory of alienation, given its prominence in contemporary social and educational theory as well as recent empirical sociological studies.

Hegel and Marx

Georg W. F. Hegel (1770–1831) in his epic work *The Phenomenology of Spirit* (1977) popularized the modern theoretical understanding of alienation using the German words *entfremdung* ("to make alien") and *entäusserung* ("to surrender or divest," as in property). Hegel utilizes both words to characterize alienation in terms of a particular historical period and culture, or "spirit" of the age, which is marked by the separation of the self from itself and cultural and spiritual disunity. Hegel's emphasis on the realm of culture, the self, and ideas inspired a wide range of contemporary work on alienation or "estrangement" in the modern self, in the spiritual realm, and in the relationship between the individual and modern cultural forms. Most significantly, Hegel was a major influence on the young Karl Marx and his own social philosophy.

Marx develops his historical materialism in opposition to Hegel's attempt to reconcile subject and object in the sphere of consciousness instead of on the ground of human material praxis. For Marx, both alienation and commodity fetishism arise *in* capitalist society and describe an inverted form of "species-being" in which human beings become dominated by the objects they produce in capitalist relations of production.

Marx argues that the worker in capitalist society is estranged in several respects: from the product and process of labor, from other workers, and from himself or herself. What is common to and underlies all these aspects of estrangement is the *process* whereby the laborer is transformed into a commodity and becomes an *object* to be bought and sold on the market like any other commodity. The laborer not only loses himself or herself in the object (product), and loses the object to the capitalist, he or she becomes an object and exists in a condition of objectification. Alienation for Marx is not only or primarily an *experience* of estrangement but a material and ontological condition—of distorted historical being formed within the capitalist relations of production. Laborers can only enter into the realm of human being, of human subjectivity, by transcending the alienated labor and ownership relations of capitalism.

In the master work of his later years, *Capital* (1867), Marx extends his earlier analysis of alienation to a thoroughgoing critique of the capitalist mode of production. His seminal critique of political economy proceeds through unraveling the answer to the central riddle of capitalist society—the true nature of the commodity. For Marx, commodification is another way to analyze the inverted/alienated subject–object world of capitalist society, in which abstract exchange value takes precedence over concrete material use value and economic (market) relations come to dominate the whole of human and social life. In capitalist societies, these economic relations are organized by the production, circulation, and exchange of objects to increase the private profit of capitalists, not to satisfy the needs and welfare of the producers. The production and exchange of these commodity-objects, an abstract historical artifact of capitalist ownership, thus become the basis and purpose of capitalist life itself, subordinating real material needs to "alien powers" and the benefits of the capitalist class.

Thus, the commodity form is analyzed by Marx as the major alienating power dominating human life in capitalist society to such an extent that only objects are endowed with value (the "fetishism" of commodities). In this inverted/alienated world, human qualities are transferred to commodities, and the characteristics of objects are transferred to human beings. Moreover, these economic forms appear to have a reality independent of the real human beings who have created them in history.

Lukács and the Frankfurt School

In *History and Class Consciousness*, Georg Lukács transforms Marx's concept of commodity fetishism into his own theory of alienation or "reification" by integrating Weber's theory of Western rationalization into Marx's philosophy of praxis. As with Marx, Lukács aims to uncover the inversion of ideological appearance over reality in capitalist societies through rigorous examination of the very cultural logic of capitalist life. However, Lukács draws on Weber to analyze this cultural logic and its ideological effects in every institution of modern society. His amalgamation of Weber's rationalization thesis and Marx's analysis of commodity fetishism comes together in a critical analysis of the "reification" of capitalist society. Lukács argues that contemporary capitalist societies are pervaded by a Weberian type of instrumental rationality that dominates human beings to such an extent that capitalist society becomes reified; individuals lose the ability to understand their own society or history. While the capitalist economic system is ultimately the basis of

this formal rationality, the reified world comes to have a relatively autonomous hold over social life, including the economy. With the development of reification, he argued, not only individual reason but also the possibility of working-class consciousness was structurally blocked without the use of critical theory. However, by opposing the reified world of formal rationality with a critical dialectical reason, Marxism could explode the realm of objectified appearances and transcend the gap between subject and object in revolution.

Lukács was one of the primary inspirations for the Frankfurt school's critical theory of modern society. In the face of fascism and the postwar spread of capitalist ideology, Max Horkheimer (with Theodor Adorno in *Dialectic of Enlightenment* [1972], Erich Fromm, Walter Benjamin, and Herbert Marcuse) combined the insights of Marx, Lukács, Sigmund Freud, Friedrich Nietzsche, and others into analyses of modern alienation that intensified and deepened the critique of uniquely modern forms of domination. Marcuse's *Eros and Civilization* (1955) and *One-Dimensional Man* (1964) and Fromm's *The Sane Society* (1955) are particularly powerful examinations of the mid- to late-20th-century alienation of self in capitalist society. However, unlike Adorno and Horkheimer, Marcuse and Fromm held out hope for the dialectical negation of alienation—for Marcuse in the aesthetic dimension and student revolt and for Fromm in the integration of self in psychoanalysis.

Freire

In educational theory, the Brazilian educator and philosopher Paulo Freire has been the most influential writer on student alienation. Freire (1921–1997) is a critical theorist in the Western Marxist tradition, and his project, his "pedagogy of the oppressed," is specifically concerned with the transcendence of alienation and oppression through the development of a critical literacy with revolutionary intent. However, unlike previous traditions of critical theorizing, Freire's educational work is intent on explicitly combining theory and practice in his philosophy itself. He established this reputation with his seminal 1972 book *Pedagogy of the Oppressed*, as well as his political practice developing and implementing literacy programs in his native Brazil and throughout the world.

At the foundation of Freire's pedagogy is a philosophical anthropology about the nature of the human being. For Freire, as for Marx, human nature is radically historical. It is only capable of being defined and understood as potentiality—of possibility within conditions of freedom. It is not possible to understand human nature abstracted from the specific and powerful social relations and structures within which we live at any given historical moment. Freire asserts, with Marx, that human nature is defined by the potential for imagination, creativity, and meaning and the free exercise of our productive powers through unalienated work. We are who we can potentially become through our capacity to think, feel, and work under conditions of our own choosing. "Human" being only becomes realized when the individual and community are actualized together in a reciprocal process.

The alienated condition of the oppressed necessitates a revolutionary pedagogy for humanization and critical consciousness. This pedagogy is no mere collection of methods or technical teaching skills to be applied within the framework of traditional schooling. For Freire, the pedagogy of the oppressed must be radically dialogical. Education for liberation cannot be imposed on or imparted to the oppressed; it can only be created with them in the *process* of humanization. Freire develops his pedagogy in contrast to traditional "banking" methods that preserve the status of the oppressed as objects, and advocates a critical and dialogical education that poses problems for students. Teacher and students in this conception work together as equals to actively solve problems about the nature of social reality and, in the process, to change this reality. If consciousness is intentional and active, authentic education cannot be based on depositing facts into it.

Later Works on Alienation

Other major works in recent educational theory and scholarship that have made significant contributions to understanding alienation in schools include Paul Willis's *Learning to Labor* (1981), Carol Gilligan's *In a Different Voice* (1982), Douglas Foley's *Learning Capitalist Culture* (1990), Donna Gaines's *Teenage Wasteland* (1990), Jane Roland Martin's *Changing the Educational Landscape* (1994), Julie Bettie's *Women Without Class* (2003), and C. J. Pascoe's *Dude You're a Fag* (2011), just to mention some of the most influential scholarship.

Analytical Psychology: Carl Jung

Carl Gustav Jung (1875–1961) was a Swiss psychiatrist and the founder of the school of analytical psychology. The son of a Swiss Reformed minister, he grew up in Basel, where he was influenced by the writings of Jacob Burckhardt and Friedrich Nietzsche. He described his formative school experiences in his autobiography, *Memories, Dreams, Reflections*. Graduating from the municipal university, he joined the staff of Eugen Bleuler at the Burghölzli Mental Hospital in Zürich, where he conducted groundbreaking studies of the psychology of schizophrenia. His word association experiments established the existence of emotional "complexes" and led to the creation of the lie detector test. An early adherent of psychoanalysis, he became its leading spokesman and developed a close relationship with Sigmund Freud. After they parted ways in 1913, Jung elaborated an alternate model of the unconscious that focused on its collective dimension, which expresses itself in an imagistic language of dreams, myths, and symbols. With its emphasis on the creative potential of the human psyche, his approach has appealed to everyday people seeking guidance in life as well as artists as diverse as the painter Jackson Pollock and the musician Sting. By way of Joseph Campbell, whose studies of world mythology reached a wide audience, Jung's theory of the archetypes helped inspire *Star Wars*, and one of them, the *persona* ("social mask"), has entered common parlance.

Jung's new psychological approach was promoted in the United States by Beatrice Hinkle, a neurologist who had studied with him in Zürich. This was during the Progressive Era, when the latest ideas from the social sciences were being applied to the problems of a modern industrial society. Many college graduates gravitated to New York City's Greenwich Village in lower Manhattan, where they worked in settlement houses and became labor activists. Some formed the Heterodoxy Club, America's first feminist organization. They also championed educational reform and, with their Montessori training, started New York's first progressive schools, such as Walden, and City and Country. They applied Jung's ideas about child development and creative self-expression in their curricula. Their focus on educating the whole child was evident in art classes and social activities conducted by a psychologically informed faculty. One of them was a school psychologist, Frances Wickes, whose cases confirmed one of Jung's (1974) key observations that "most of the nervous disturbances in childhood can be traced back to a disturbed psychic atmosphere in the home" (p. 39).

Jung was invited to speak at the International Congresses of Education held at Territet, Switzerland (1923), London (1924), and Heidelberg (1925). These were organized by Beatrice Ensor, who had helped found the International Bureau of Education in Geneva under the auspices of the Rousseau Institute, which was later reorganized with Jean Piaget as one of its codirectors.

In his later years, Jung continued to lecture and maintain a busy analytical practice while exploring the relationship of psychology to alchemy, Buddhism, and physics. After World War II, he took a keen interest in the UFO (unidentified flying objects) craze and interpreted it as an emerging myth of the Nuclear Age. The first Jungian training institute was founded in 1948 and is now part of an international network of Jungian organizations.

Contributions to Educational Theory and Practice

Modern ideas about education began with the writings of Jean-Jacques Rousseau (1712–1778), who emphasized the importance of freeing the child from the strict discipline and rote learning common at the time. His ideas were developed further by another Swiss, the pedagogue Johann Heinrich Pestalozzi (1746–1827), who opened up schools that adopted a holistic approach that fostered the emotional and social as well as cognitive development of the child. Jung adapted the 19th-century German educational ideal of *Bildung* ("cultivation") for the 20th century by extending it to include a person's entire life span. "The way of successive assimilations . . . leads in the end to that distant goal which may perhaps have been the first urge to life: the complete actualization of the whole human being, that is, individuation" (Jung, 1974, p. 160).

Jung (1974) felt that the teacher's most important influence was emotional rather than intellectual.

> An understanding heart is everything in a teacher, and cannot be esteemed highly enough . . . the curriculum is so much necessary raw material, but warmth is the vital element for the growing plant and for the soul of the child. (p. 144)

He emphasized what he called the "self-education of the educator." To develop psychologically mature teachers, he advocated that they become aware of their dream life to understand their own complexes and their effect on students. Although this particular suggestion was never adopted, education courses and workshops now routinely address the psychological training of teachers.

Jung's most important contribution to practical psychology was his theory of extraverted and introverted personality types. Although there is no such thing as a pure type, people tend to exhibit a primary orientation to either the outer world or their inner, subjective world. In an extraverted society such as the United States, introversion is routinely misinterpreted as shyness and labeled as a negative trait. Besides these general types, Jung further distinguished four different psychological functions, one of which becomes dominant during a person's development: (1) thinking (what something means), (2) feeling (what its value is), (3) sensation (what it is), and (4) intuition (what it might become). Personality assessment tests are now routinely administered in business and counseling, one of the most popular being the Myers-Briggs, which was developed by followers of Jung.

A major development in educational psychology that generally supports Jung's discoveries has been the work of Howard Gardner and his theory of "multiple intelligences." Although there is no one-to-one correlation, both scholars do postulate a variety of naturally occurring functions or intelligences that need to be recognized by educators. More recently, Gardner has considered the possibility of spiritual or existential intelligences that would lend support to Jung's idea that a religious instinct is one core component of the human psyche.

An appreciation of multiple intelligences and an awareness of the changing nature of literacy in a new, visual culture means that teachers must adjust their practices. They must learn to cultivate the imagination as well as the intellect of their students. Jung's work on the role of symbols in history and culture can be a unique tool to do just that. Activities that incorporate an art component can be not only emotionally satisfying for students, especially for those struggling academically, but also a valuable diagnostic tool for teachers trained in their use. Literary and film studies can benefit from a Jungian approach by including a consideration of archetypes such as the "hero" and the "shadow" (the "Other" who represents the unacceptable aspects of oneself). For example, a study of the personalities and the scapegoating in William Golding's novel *Lord of the Flies* can be deepened by an understanding of Jungian psychology.

Jung's influence on the field of education has more often been indirect than direct. His pioneering effort to introduce educators to the insights of psychology can be seen in the courses now required for an education degree. His observation that the entire family unit is the locus of serious childhood problems is a fundamental tenet of family therapy. His special concern for the learning potential of the second half of life is now reflected in the proliferation of adult education courses. Jung's broadly humanistic approach, emphasizing the cultivation of the innate capacity for learning, is in contrast to the reliance on standardized testing that is characteristic of the data-driven agenda of contemporary American education.

Anthropology of Education: Main Traditions and Issues

It is generally said that the anthropology of education, as a subfield of the discipline, began with a conference bringing together some senior anthropologists and professionals from the world of American schooling. The proceedings of this conference were published in 1955; they were edited by George Spindler, whose leadership established the field. But it is also true that anthropologists had been interested in education from the earliest days of the discipline. As they noted the variability of human ways, they began to wonder how infants with the potential to learn any language or participate in any society transform into adults with specific forms of knowledge, habits, and blinders to other forms of knowledge. Depending on the theoretical inclinations of the authors, the stress was put on psychological processes most powerfully active in the first few years of what was often labeled "enculturation."

Margaret Mead's *Coming of Age in Samoa*, published in 1928, may be considered the first educational ethnography of that early period. It inaugurated a large literature on what came to be known as "learning one's culture," and it had a massive influence on the politics and practices of American schooling. During the same period, another group of anthropologists, mostly from England, came to education because of their interest in initiation rituals, particularly when initiation involves the imparting of esoteric knowledge. From that angle, becoming a particular type of adult in any complex society with multiple roles necessarily involves explicit processes and institutions that produce internal segmentation and differentiation. In such societies, one does not learn "one's culture," since one only learns the kind of knowledge particular to one's place. Anthropologists of this tradition often write about "socialization" into "roles" and claim the French sociologist Émile Durkheim, rather than Sigmund Freud, as their inspiration.

Durkheim (1922/1956) wrote extensively about schooling and actively participated in the intellectual movements that led to the establishment of French public schools at the turn of the 20th century. American anthropologists did not deliberately turn to American schooling until the 1950s, in the wake of their success in influencing major policy decisions regarding the postwar political reconstitution of Japan. Mead had been involved in that work, and she was quite sure that anthropology could and should be applied to "the problems of our times." She had written about school teachers in the 1940s and was one of the prime movers of the conference that began the institutionalizing of the new subfield. She encouraged its establishment in the leading schools of education. Soon, at Columbia, Stanford, the University of Pennsylvania, and others, new programs attracted both young and seasoned anthropologists, students, and, perhaps most fatefully, school professionals who saw in the emerging work a powerful alternative to the then usual ways of learning about public school teaching, about students, and about thinking through how to reform schooling. Many professionals were initially attracted by the ways of knowing that anthropology took somewhat for granted. Against the experimental methods of most psychology and the hypothetico-deductive methods of much of sociology, anthropology offered "ethnography" as an inductive methodology for discovering what human beings, including schoolchildren and teachers, can do, why, and how.

The Anthropology of the Failures of American Schooling

The activist and reformist stance of the 1954 conference remains characteristic of the anthropology of education and, arguably, one of its weaknesses. By the 1960s, anthropologists, as well as some sociologists who also used ethnographic methodologies, actively participated in the elaboration of the rationales for many of the most significant policies collectively known as "The Great Society," particularly programs such as Head Start and the public television program *Sesame Street*, which looked at

schooling, or preparation for schooling, for part of the solution to the problems that had been recognized. Anthropologists soon also became the leading critics of some of these rationales, particularly when these led to policies designed to "remedy" the consequences of various "deprivations." Given that these rationales were often grounded in the work of developmental and cognitive psychologists who had hypothesized that failure in language socialization might "explain" school failure, and thus poverty, much of the anthropological work of the period developed alternate theories about, and methods for studying, the relationship of language and culture to the production and assessment of knowledge. In response to much research by psychologists and sociologists, anthropologists of education focused most of their attention on where deprivation supposedly started—they went into homes and communities, to find out how, in the details of their lives, people managed the complex interaction between local conditions, experiences in school, and eventual adult careers. For the following 30 years at least, most research and debate in the field addressed the matters of social and cultural reproduction that were driving reformist concerns.

Typical of these evolving concerns was the controversial work of a famous anthropologist, Oscar Lewis, and the subsequent critique of this work by other anthropologists. Lewis brought to his entry into public policy well-developed theories of social structure and its impact on socialization and the shaping of adult personalities. These led him to propose, in the mid-1960s, that the difficulties Puerto Ricans appeared to have in the United States had something to do with a "culture of poverty" (Lewis, 1966). Lewis had not written specifically about education and schooling, but his work resonated powerfully with many in the policy field, perhaps because it fitted well with other psychosocial theories and perhaps also, more darkly, because it fitted well with various stereotypes—as some critics charged.

In many ways, Lewis's work remains significant because it inaugurated a problematic that still guides much research in the anthropology of education. There were many versions of Lewis's hypothesis in the 1960s, most of which centered on the relationship between the language of the home, the language of the child, and the language of the school. Psychologists and sociologists proposed various mechanisms that would explain why many children have difficulty in school and how to address these difficulties. Anthropologists generally were not so sure, and their observations in homes, schools, streets, and communities led them to propose other kinds of mechanisms. Much of this ethnographic work ended with calls to reform schooling to build on what Luis Moll (2005) eventually called the "funds of knowledge" students gain through their participation in families and communities. The first decade of this work established that what can look like disabilities in, for example, language processing when seen from the point of view of psychology may simply be the product of methodologies that make sensible responses to local conditions look like disabilities. William Labov (1982) remains famous for having demonstrated that the "silence" of Black children in the schools of the 1940s and 1950s had little to do with inner abilities or poor parenting and much to do with their relationships with White teachers. This reticence made sense in precivil rights schools, just as defiant opposition might make sense in urban schools half a century later, as noted by John Ogbu and Herbert Simons (1988).

This early research on language use in classrooms opened the way to bringing forward the difficulties of immigrant children entering school with a language other than English and then being tested on their abilities for schooling in English. Over the following decade, the focus on language processing was broadened to include concerns with "cultural" mismatches between children and schools (see, e.g., the work of Shirley Brice Heath, 1983). Even as academic anthropologists conducted a vigorous critique of the concept of "culture," it became one of the central organizing themes of proposals for school reform. As the anthropology of education became more fully integrated within reform politics in the United States, it became essential in the justification for bilingual or multicultural education, for example. Some of this new research used concepts such as social or cultural "capital," with the suggestion that the lack of such capital might explain various achievement gaps. At its best, such work escapes the problems associated with the use of "culture" as explanation. But it often collapses back into an assumption that "capital," like "culture," is a property of the individual child.

But, some argued, things are not really so clear-cut. Most powerful in making anthropologists face what is troublesome about schooling and its outcomes has been Pierre Bourdieu's work on the place of schooling in the reproduction of contemporary complex societies (Bourdieu & Passeron, 1977).

Bourdieu presented strong evidence that the production of legitimated school failure is an essential feature of modern schooling and, by implication, one that is not amenable to reform in curriculum or pedagogy. Students, in this perspective, do not fail in school (and thus fail to get into the better positions of a modern society) because of either personal disability or cultural mismatches but because schools are organized to produce failure. Simply put, all recent political systems that present themselves as meritocracies, particularly when they attempt to combat all forms of birth privileges (whether based in race, ethnicity, class, gender, etc.), have given schools the responsibility of assigning merit in politically unassailable terms. Practically, this means that schools must fail most students and must ensure that the scope of failure increases as one reaches the most respected, powerful, or remunerative of positions. Many teachers are unhappy about the situation, but they are also always "agents of the state," as Michel Foucault argued. Bourdieu proposed that the mechanisms through which those who fail in school (and indeed those who succeed) include a mediating process between social conditions and outcomes. Bourdieu described this process as involving a "habitus," which he defines as a "disposition inculcated in the earliest years of life and constantly reinforced by calls to order from the group" (Bourdieu, 1970/1977, pp. 14–15). Others, such as Hervé Varenne and Ray McDermott, have argued that it is unnecessary to invoke such a mediating process and, worse, that it can lead to representing those who fail in school as ignorant and in need of remediation. This can open the way to a return to "culture of poverty" explanations. While most still eschew the phrase and use other labels, invoking habitus as explanation for school failure remains commonsensical for some anthropologists.

One alternative is to reveal how the mechanisms of school failure are produced in the moment-to-moment construction of the most routine of school sequences (McDermott & Tylbor, 1983). This approach may demonstrate the extent of what Bourdieu had called "symbolic violence" in schooling. It also insists that all people submitted to this violence have a practical intelligence that cannot be minimized. From this perspective, the problem is not that children do not learn how to read because of some internal properties or psychological deficit. The problem arises as the children are publicly identified, by an agent of the state, as not knowing how to read in a certain way at a certain time and then are treated, for future politically legitimate purposes, on the basis of this identification, however loosely related it is to the practical task at hand. Approaching schooling from this perspective has produced abundant ethnographic evidence that those who live and raise their children in the worst of conditions can talk about the barriers they encounter and act deliberately to cross them. This suggests the reality of forms of practical awareness that observers can easily miss, particularly since the forms of talk and action used by those who are characterized as failures may not correspond to their own. This opens interesting questions about what is technically called metacommunication and metapragmatics—questions that remain wide open.

Initially, the work on the tactics of the poor was presented as evidence of practical "resistance" (Willis, 1977). This work has sometimes been criticized for romanticizing the condition of the poor and oppressed. But the best of the work does not imply that resistance will be successful in reforming oppressing situations. Rather, it insists that the oppressed have, minimally, some understanding of their conditions, that they are active, and that reform does not need to proceed through the advantaged leading them through various programs designed to raise consciousness or understanding. The classical anthropological stance, one the discipline inherits from the early work of Franz Boas or Bronisław Malinowski, is that the poor, like the so-called primitives or colonialized natives, probably understand their physical, social, and political conditions better than any observer and that scholarly or policy-oriented discussion of that understanding requires an extensive period of learning from the people themselves as they produce their own lives—what came to be known as extended, systematic, "ethnographic fieldwork."

Ways of Knowing: Classic Ethnography and Its Anthropological Critics

The anthropology of education had inherited from its roots in Boasian culture theory a strong sense that the way to get to know people is to spend time with them, in the routine settings of their everyday lives. The field also inherited, from Mead perhaps more than anyone else, the sense that what one learned through the resulting ethnography was best reported in an evocative fashion, with direct statements about the application of the new knowledge

to issues current among popular audiences. Mead insisted, with a surprising amount of success, that rare if not unique practices in faraway lands would help us with a more systematic understanding of common practices in the United States that appear "natural" to humanity but can be shown not to be so. As the field evolved into what became known as "culture and personality," many anthropologists also insisted that their reports indicate how practices and patterns affected the lives of individuals. The most powerful work of that period, and one of the earlier ethnographic reports in the anthropology of education, may be a 1963 report on the travails of American adolescents in school, which Jules Henry provocatively titled *Culture Against Man.*

As Henry published his report, several lines of critique were transforming the field. These were theoretical critiques of methodology: What sort of knowledge did what kind of ethnography produce? And, most radically, did ethnographic work produce the kind of knowledge that had the very kind of practical use, and indeed political use, earlier anthropologists were convinced it had? Initially, as mentioned earlier, many feared the focus on individual suffering, when this focus led to assumptions about internalization and misunderstanding that were actually built into all cultural anthropology, as well as sociology influenced by the work of Talcott Parsons. This theoretical critique, as such, did not indicate how to modify methodologies. But new developments opened alternative routes that had not yet been systematically explored. Early ethnographic methods could not be described easily, and the work that was published appeared impressionistic. In the 1940s, Gregory Bateson, when working with Mead in Bali, had explored new techniques for recording and analysis made possible by film. These approaches did not have a mainstream impact until the entry of sociolinguists into the world of the anthropology of education. Inspired by Malinowski's late work on the analysis of texts in use, they insisted that classic issues in determining the "meaning" of linguistic forms and texts could be addressed systematically by examining how exactly words were used in practical situations. The greater availability of audio and video recorders allowed for just the kind of analyses that Malinowski and Bateson, as well as William Labov, Dell Hymes, and other figures, had called for. This led to a flourishing of what came to be known as "micro-ethnography"—often to the dismay of those who developed the techniques as a privileged form of doing just what Mead had done: using the rare and unique to make broad points about the organization of modernity and the constraints it can place on people. Most ambitious among the early efforts may be McDermott's use of a few seconds of interaction between an Anglo teacher and a Puerto Rican child to cast doubt on the broad "explanations" of school failure that invoked "cultural mismatches."

In parallel, a more radical critique of ethnography was being developed within anthropology itself as many anthropologists challenged the very possibility of gaining systematic knowledge about human beings. Clifford Geertz (possibly the most influential American anthropologist of his generation) and his students argued that all anthropologists could do is "interpret" what they experienced in the field (Geertz, 1973). They proposed that the discipline be presented as a branch of the humanities rather than as a social science and, thereby, fundamentally challenged the Boasian position. It would be fundamentally impossible to learn about human beings in what most distinguished them from other animals—that is, in their production of symbolic means to address their environment (in other words, their "culture"). Thus, one could not discover (rather than imagine or interpret) what human beings can do. The kind of close participation and intensive observation that had been the hallmark of anthropology only produced a personal experience for the ethnographer that could not be translated into general knowledge. If so, then cultural anthropology should not be applied either internationally to issues in colonial administration and development work or, by implication, to issues of educational policy in the United States. Attempting to apply anthropology ended with the co-option of the anthropologist into the structures of entrenched power.

Anthropologists were left in a difficult position. The Geertzian critique made sense, particularly as it was developed by Michel Foucault. Many in the field started to "deconstruct" older texts in order to highlight how they were grounded in unexamined ideas about sex or gender, race, ethnicity, ability, and so on. They called for research that would be deliberately sensitive to these matters. But, like those who accepted the Geertzian critique of ethnography, they did not offer clear methodologies or techniques. Many actually began to argue that ethnography was too narrow and that what was called for was "qualitative" methodologies. But these remained very hard

to specify or justify. And their relevance to a deeper understanding of schooling, and education, could easily be questioned—as it soon was.

Recapturing an Anthropology of Education

The methodological debates sometimes eclipsed the more fundamental conversations about culture and poverty, including the cultural production of poverty and cultural productions by people caught in poverty and other difficult conditions. However, these conversations led to the reopening of a preliminary question that the rush toward policy relevance elided: What is the anthropology of education an anthropology *of*? One can also ask what a concern with social reproduction in modern societies has to do with education. Given the central role of schooling in this reproduction, it is not surprising that most research in the anthropology of education takes place in and around schools, and particularly around American schooling. It is not surprising either that the questions anthropologists ask are the very questions the people of the school ask.

The initial stance once taken by Mead remains. She and the other anthropologists who organized the 1954 conference had invited superintendents and other professionals to tell anthropologists what they needed help with. A half-century later, most research in anthropology is driven by the positionality of the people who fund it and to whom it is addressed—and these mostly consist of the people intimately concerned with the school, from teachers to administrators to policymakers in the many layers of government concerned with schooling.

The focus on American school policy is understandable, but it is also quite limiting. An early version of the critique was formulated by a historian, Lawrence Cremin, who was himself powerfully influenced by anthropologists at Columbia and particularly by Mead. Cremin was instrumental in the establishment and staffing of the program in the anthropology of education at Columbia's Teachers College. He also began to wonder what a history of education should be a history *of*? He answered decisively that it should not be only a history of schooling (Cremin, 1976). The same question is now being asked of the anthropology of education and the same answer given (see Varenne, 2007). As the earliest anthropologists had well known, it can never be a single institution that transforms an infant into a particular adult able to participate in particular positions for particular purposes at particular times, and it is never a mechanical process.

In recent years, the most powerful work moving anthropologists back to this fundamental intuition may be that of Jean Lave and her colleagues. Lave was one of the several anthropologists Michael Cole, a cognitive psychologist, brought together in his Laboratory of Comparative Human Cognition. He asked them to help him conduct a systematic critique of theorizing in cognitive psychology, particularly as it is concerned with the identification of inner psychological abilities and with learning. Given that human beings always use and reveal their cognition in the sites of their interactions with other human beings, it does not make sense to explore this cognition in isolation, apart from interaction. Taking such a stance has major methodological consequences as it requires one to research learning in the social settings where what is to be learned is used. Ethnography becomes the privileged method, and anthropology, with its long tradition of developing and critiquing the method, becomes the sensible discipline to engage in the renewal of cognitive studies, particularly as it concerns learning and, indeed, education.

Lave first went to Liberia to observe tailors and their apprentices as they dealt with complex mathematical calculations. She then went into American supermarkets to observe other people doing other kinds of calculations (Lave, 1988). Her colleagues and others started looking at midwives around the world, alcoholics, navigators, and others, as they developed complex forms of knowledge through their participation in what she called "communities of practice." The phrase was introduced in her work with Etienne Wenger (1991) and has had a controversial history when further writing, particularly by Wenger, did not quite mention that the original formulation emphasizes movement, transformation, control, and identification and was not simply pointing to a more comfortable environment for effective learning. Lave's work has contributed to the renewal of social research in general that is also being moved by the works of ethnomethodologists like Harold Garfinkel (2002) and anthropologists inspired by his work, such as Bruno Latour (2005). This emerging tradition has had a distinct impact on recent anthropology of education, particularly because it addresses the broad contexts of educational activity, including schooling, as in the work of Jill Koyama (2010), and because it offers new justifications for

ethnographic research. This work allows anthropologists to argue more systematically that schooling, with its state-prescribed curricula and pedagogies, is but a special case of universal efforts to transform conditions or to prevent the transformation of conditions. Education, these new research traditions establish, is indeed a ubiquitous phenomenon that even includes the education about schooling and its reform that is conducted not only in the centers of political power or influence but also in the familial and communal peripheries where curricula and pedagogies are discussed. To mention but one recent ethnography among many, Fida Adely (2012) has recently reported on adolescent girls in a Jordanian high school as they discuss the various forms of Islam by which they are multiply confronted. Adely's work is paradigmatic of the work of a new generation of scholars who demonstrate what can be done when one frees oneself from the narrow problematics proposed by school people to anthropologists.

This recent work is adding a significant twist to Cole's and Lave's concerns. Given their moment in the intellectual history of cognitive studies and the political history of the United States, it made sense to place their concerns under the banner of renewing the theories of "learning." It thus made sense to look at tasks like learning mathematics and syllogistic thinking, for it seems clear that one "learns" how to calculate proportions or how to navigate a boat. But it is not so clear that one "learns" Islam or Christianity or secular humanism. "Becoming" a Muslim, Christian, humanist, and so on, is more akin to entering a world of murky debates than to absorbing a worldview. It is not so much a matter of learning skills or dispositions as a matter of placing oneself in some relation with the various versions of the particular "religion(s)."

Future Directions: Developing New Ways of Knowing to Face New Challenges

When Mead went to Samoa or when George Spindler entered into dialogue with school people in America, the issues may have appeared simple. People learned their culture in everyday interaction, and enlightened professional intervention might guide this learning to build a better democracy. John Dewey had prefigured the ideological movement within which anthropological research on education easily fit.

Half a century later, things are not so clear, either on the theoretical or on the political front. Dewey's call for an education that fosters democracy remains, but the emphasis on shaping minds and on learning is now faced with the evidence that minds are not quite so amenable to shaping and that learning is only one aspect of education. Human beings, as they transform themselves and their environments, do not simply learn. They also question, analyze, seek help, explain, attempt to convince, instruct, teach, assess, and so forth. The only plausible postulate at this moment in the history of the field is that all human beings are involved in this complex process of education, not just a few specialists. The correlate of this postulate is that education is an ongoing process throughout the life span and not only a temporary moment in life (whether the first years of life or the years of schooling). From the time an infant first encounters her parents to the time when, at the end of her life, she enters the final seconds of consciousness, the conditions, contexts, and communities she will encounter would have been changing, often in fundamental ways—whether because of war, migration, natural disasters, or (more prosaically in the world of the past two centuries) new technologies. Tablet computers, for example—like steam engines, electricity, and telephones had done—present new challenges and new opportunities for questioning, analyzing, and assessing. The challenges to the field are all the greater now that the radical critiques of ethnography have made it more and more difficult to reach the audiences that the anthropology of education, since its founding, has struggled to reach. At the turn of the 21st century, these audiences appear only to trust "data-driven" research using large "data sets" drawn from the population to whom a policy is directed. It appears fantastic that anthropologists should claim that one learns best about the most common issues in the life around us by looking systematically at rare practices in populations far removed from the ones of concern. "Policy cannot be drawn from anecdotes" is something anthropologists keep hearing from their audiences, and they have not found an effective retort. The fact that the qualitative research of the past 30 years often presents itself as reporting on the pluralities of individuals and their (in the aggregate) interpretations actually reinvigorates focus on systematic sampling and the like and also strengthens the tendency to dismiss earlier ethnographic research that had always been stronger at sketching practices, patterns, and organizations than at outlining what the individual persons living these actually experienced.

Two related responses are taking shape in the anthropology of education. They are rooted in a systematic critique of the hypothetico-deductive methods that are now again dominant. What is known as "ethnomethodology" began in the 1950s as an empirical response to Parsons and his attempts to draw grand theories of action (Parsons & Shils, 1951). The critique was led by Harold Garfinkel, who inspired a major body of work that demonstrated again and again that only careful observation of people in their routine settings could tell us anything about what human beings can do and what they actually do. In so doing, Garfinkel offered a new justification for the old Boasian argument about the special value of anthropological ways of knowing. Research inspired by ethnomethodology keeps illustrating, first, that human beings are more imaginative at adapting in environments than theoreticians—or even local practitioners—can imagine and, second, that there are systematic methods for discovering these adaptations and reporting on the discoveries. Boas made the argument cross-culturally and cross-historically; the new research is making the same argument by highlighting the multiplicities of adaptations to conditions within modernity itself. One does not need to go around the world to find the rare and the unique. One only has to look carefully at what is happening down the street, if not down the corridor. The most significant recent development in this recovery of systematic ethnography draws inspiration from the work of Latour, who showed what can be discovered by conducting ethnography in biological research laboratories or in other national elite institutions. Research such as Koyama's may lead to the moment when anthropological ways of knowing can again participate at the center of conversations about who we are, what we do, and how we might reform the patterns that make individuals suffer—at the broadest of levels.

An anthropology of education must thus be an anthropology of the deliberate attempts to face and transform conditions, whether to reproduce traditions or to produce new ones. These attempts can involve a few people in small locales, or they can involve whole populations searching for new political forms even as they attempt to reform institutions or practices that are shown not to be leading where earlier generations had hoped they would lead. In the human world of the past few 100 years, and as the ongoing experiment that is public schooling continues and spreads around the globe, it is clear that any anthropology of education will also be an anthropology of schooling that has confronted the methodological and theoretical difficulties the evolution of the field has made salient. But precisely because an anthropology of schooling is so important to our future, it must also remain encompassed by an anthropology of education.

Apple, Michael

Michael Apple is often described as the world's leading sociologist of education. He was born in Paterson, New Jersey, in 1942. He began work as a substitute teacher at age 19 and later became a teacher union organizer and political activist. Since 1970, he has worked at the University of Wisconsin–Madison and is now the John Bascom Professor of Curriculum and Instruction and Educational Policy Studies. Apple's work revolves around three main interrelated axes—(1) the cultural politics of education, (2) equity and social justice, (3) and democracy and critical pedagogy. These concerns interweave over a 40-year period from *Educational Evaluation: Analysis and Responsibility* (1974) to *Can Education Change Society?* (2013). At the heart of this work is the simple question: What counts as official knowledge? That is, on the one hand: What is the school curriculum? Who decides? Whose knowledge is taught? And how do those decisions relate to economic structures? And on the other: What is the relationship of the curriculum to the life experience of learners? And what are its implications for social equity? Thus, a considerable body of Apple's work focuses on contestations over what is to count as school knowledge. In his early work, a key point of emphasis was the complex relations between state politics and the textbook industry, which is discussed in the 1991 book edited by Apple and Linda Christian-Smith, *The Politics of the Textbook*. According to Apple, the textbook is a neglected basis for understanding how legitimate culture is defined in the classroom, particularly as the state becomes more involved in determining the types of knowledge to be taught. In more recent work, he examines commodified educational technologies and pedagogies, focusing on particular examples like the introduction of Channel One, a privately run TV news program that includes advertising, into schools. As he points out, restless capital is ever eager to exploit new market opportunities and make a profit, through the production of hardware, software, and curricular materials for home learning. This entry discusses Apple's analysis of a conservative alliance in education and its implications for equal opportunity, his commitment to democracy in education, and his emphasis on the importance of viewing school culture and policy in a historical context.

Conservative Restoration

Apple's later work undertakes a careful and complex analysis of the politics of conservative restoration, both its "residual" and "emergent" forms, and its constituent parties: neoliberals, neoconservatives, authoritarian populists, the new middle class, and the Christian right. He is very clear that this ideological formation is *built* or *constructed*. He examines the shifting alliances among these groups around educational issues and their attempts to establish a "New Right" educational common sense, or a translation of economic and religious doctrines into an *organic* ideology, and therefore to dictate public discourse around issues of race, class, and gender. This is set over and against a nuanced analysis of the crisis of the *social democratic accord*, within which government became the arena for establishing the conditions for more equal opportunity in education. He

acknowledges both the successes of the New Right, and the failures of the social democratic accord, and the ability of the right to co-opt and translate the everyday concerns of many parents into a set of simple and powerful and *popular* messages for educational reform. However, in relation to these successes and failures, he also seeks to capture and analyze the struggles, resistances, and creativity of those teachers and schools that exploit opportunities to think and act differently about education, for example, in *Democratic Schools* (with James Beane, 2000) and *The Subaltern Speak: Curriculum Power and Education* (with Kristen Buras, 2006). The struggles attended to here focus around recurrent conflicts between *person rights* and *property rights*, between equity and efficiency, welfare and responsibility—that is, "freedom to" as against "freedom from." However, these struggles, he argues, cannot be articulated at the theoretical level. Apple often refers to himself as a secretary—recording and representing the voices of those who struggle against oppression and "common sense"—a correspondent of hope. Running through this history of enacted critique, there is the "language of possibility"—the possibility of thinking "otherwise," of democracy in education, of "democratic schools," and "a democratic way of life" (Apple, 2000, p. 7). Nonetheless, as he is at pains to point out, this "language of possibility" "must also be grounded in an unromantic appraisal of the circumstances in which we find ourselves" (Apple, 1986, p. 178). He takes up the language of possibility in sustained fashion in his 2013 book *Can Education Change Society*? Critique and possibility are grounded for him within a history of struggles, that is a history of achievements as well as of defeats and setbacks. One of the things that make his work attractive to so many scholars and students is this critical opportunism—recognizing what might be done, even while remaining fully aware of the inauspicious forces of circumstance.

A Decentered Unity

Just as he is clear about the complicated and sometimes unstable alliances that make up the New Right, Apple sees the radical alternatives to this hegemonic block as what he calls a "decentered unity," a loose and sometimes uneasy grouping of counterhegemonic movements and organizations with shifting perspectives and goals, which are not immune to racist and sexist tendencies. The tensions and contradictions of policy and political interest are specified in a number of ways in Apple's analyses. For example, with Tom Pedroni, he looks at the support of Black parents in Milwaukee for educational vouchers, and more generally, in a number of papers, he considers the complexities of Black homeschooling. He is certainly not unsympathetic to the fears and aspirations of Black parents whose children are marginalized and abused in public schools, and who seek alternative possibilities for educational success, but he is also concerned about the long-term implications of such moves and policies for public schooling and the possibility of achieving a democratic education system.

Apple's work is continually grounded in "worked through" examples. In *Cultural Politics and Education* (1996), he and Anita Oliver examine the formation of a conservative agenda in one school district, making clear the contradictory complexities involved. In contrast, he has written several pieces (some with Luis Armand Gandin) on the Citizen School Project in Porto Allegre, Brazil, and the attempts to engage the local community both in local educational administration and in changing classroom practices.

Apple is often referred to as a critical pedagogue or neo-Marxist, and both labels are to a degree appropriate, but he is always willing to draw on a variety of theoretical tools and positions to achieve his analytical ends—"to think neo and post together" as he puts it. He is also clear about his debts to Antonio Gramsci, Raymond Williams, and Paulo Freire. If he is anything, he is a Gramscian: He is concerned about content; about political literacy; about political struggles in relation to common sense, practical consciousness, and hegemony (*Official Knowledge*, 2000); and about using theory to understand practice. He argues that economic dominance is "coupled" to "political, moral, and intellectual leadership." His work is founded on "concrete historical analysis" and always begins from the complexities of human experience rather than from theory. Apple's work is historical, and it represents the complex and extended processes of struggle and compromise, the temporary nature of social authority, focusing on cultural questions as well as material ones and avoiding a necessitarian logic.

Criticism and Activism

Critics from orthodox Marxism tend to focus not only on Apple's eclecticism, especially in recent

work, but also on his refusal to simplify—that is, his commitment to nuance and complexity, his emphasis on culture, his unwillingness to give straightforward privilege to class in his analysis, and his refusal to give value to abstract theory for its own sake.

It is possible to fully grasp and appreciate Apple's work only by going beyond his writing. To concentrate on the texts is to understand only part of what they represent and whom they represent. They not only present a body of careful research and incisive scholarship, they are also political interventions, irritations, and challenges. Indeed, Apple often appears in his texts: *Teachers and Texts* begins "On a trip to Washington, D.C., recently, I visited an elementary school less than a mile from the White House." He is an eyewitness to and a participant in the politics of education. He is an activist from his trade union origins to the present day. He travels widely to speak about and speak to contemporary issues. Apple's work is defined by totality and detail, sweep and grounding, theory and practice, global and local, personal troubles and public issues—the work of the *sociological imagination*, and the escape from stultifying orthodoxies. This is an ongoing project and a set of continuing struggles.

Aptitude–Treatment Interactions: Evolution of Research

Beginning in the 1960s and continuing through the 1980s, the educational psychologists Lee J. Cronbach and Richard E. Snow spearheaded a program of research connecting key ideas from the scientific disciplines of differential psychology, which looks at the differences among individuals and groups, and experimental psychology, which uses empirical principles and procedures. As Cronbach argued in a seminal paper addressed to the American Psychological Association in 1975, research in these two disciplines had heretofore progressed independently, with different foci and traditions, though both were contributing important understandings to the domains of teaching and learning (see also earlier writing on this topic, e.g., Cronbach, 1957, 1967). Snow had begun examining the effects of instructional treatments on performance as a doctoral student at Purdue University. He joined Cronbach at Stanford University in 1966, and together they founded the Stanford Aptitude Project to study the extent to which student performance under different instructional conditions depended on individual differences.

The culmination of that work was a scholarly book that examined and critiqued extant literature, titled *Aptitudes and Instructional Methods: A Handbook for Research on Interactions* (Cronbach & Snow, 1977). Given the stature of the authors, their reputations for exceptionally rigorous methodological critique, and the number of years they took to complete this volume, its message for ongoing research and practice in the fields of education and psychology was much anticipated. The book reported extensive evidence to support a theory about designing instructional treatments to fit different patterns of aptitude. Aptitude was defined broadly, to include any personal characteristic predictive of response to instruction in a particular educational situation (i.e., an aptitude is not limited to scores on a test of ability but can be, e.g., a work style or a personality trait). Aptitude–treatment interactions, or ATI, are the technical representations of this predictive effect; in the most general terms, studies finding ATI indicate that students with one level of aptitude perform better with a given form of instruction than those with other levels and, often,

vice versa. Although Cronbach and Snow demonstrated the ubiquity of ATI in educational experiments, the many flawed designs and methodological problems they found in reviewing the research led them to emphasize improved rigor in the handbook at least as much as substantive results. This entry discusses the research that has further developed Cronbach and Snow's ideas on individual differences in learning, how these ideas have been put to use in the classroom, and recent educational trends based on ATI theory.

Unfortunately, the anticipated practical use of Cronbach and Snow's handbook was never realized. Instead of designing more rigorous studies that might establish consistent results for given ATI hypotheses as Cronbach and Snow intended, ensuing generations of educational psychologists have, with some exceptions, abandoned the pursuit. Instead, subsequent scholarship has redefined the ATI phenomenon and design to better explicate underlying theory that might provide guidelines for teaching and instructional practice. Reconceptualizations focus on processes that occur between pre- and postexperiment assessments, both within students (aptitude processes) and treatments (instructional processes and procedures). Modern research in the tradition of ATI attempts to understand how and why different learners respond to certain instructional methods more than others: why some learners perform better, whereas others perform worse, under the same treatments. It also seeks to provide a theoretical or a conceptual framework for understanding why a specific instruction is more or less effective, given different learners' aptitudes.

Adapting Instruction to Individual Differences

The key premise of the ATI paradigm continues to be that stipulated by Cronbach in his landmark address; namely, that instruction should be adapted according to individual differences in individuals or groups of learners. However, aptitudes are now seen as "complexes," or profiles of characteristics, that account for the end state of learners. They are likewise defined as the *capacities* of learners to gain proficiency. An assumption is that learners bring to a task a unique set of propensities or aptitudes that will lead them to react in a particular way to the method and content presented in a particular instructional situation.

One of the more enduring ATI results reported by Cronbach and Snow is that learners classified as lower or higher in general intellectual ability differentially benefit from more or less structured methods of instruction. Lower-ability learners perform better when they receive a "direct" form of instruction that provides structured guidelines for completing tasks, as explained by a teacher or the task's explicit instructions. The evidence suggests that these instructions often support lower-ability learners sufficiently to reduce the cognitive burden. In contrast, higher-ability learners tend to benefit when given indirect instruction that is less structured. When asked to push harder, and "discover" key principles in primarily "learner-centered" tasks, these learners can work their way through problems independently or in concert with peers. Similar examples of ATI with more or less structured learning tasks have been reported with some affect variables such as anxiety and reactivity, and some motivational orientations, such as mastery or performance orientation (see Corno et al., 2002).

Current research focuses on explanations for results such as these, extracting consistent patterns from a variety of studies, making sharp distinctions between microlevel instructional processes, and moving interventions into natural settings. Work on the practical side seeks ways to moderate and mitigate ATI effects; one example is the professional movement to promote "differentiated instruction" (see, e.g., Tomlinson & Imbeau, 2010). Within the broader category of adaptive educational opportunities (Corno, 2008), differentiation promises a solution to the practical dilemma that teachers must instruct students as class groups at the same time that they hope to treat them as individuals within a class. One principle of differentiated practice is that there are many different hypothetically beneficial instructional approaches suitable for different learning profiles; if the teacher cannot reach students one way, another form of instruction may be tried. Differentiated instruction thus aims to capitalize on students' strengths while circumventing or compensating for weaknesses.

An important assumption of models for differentiating is that, although students vary in their readiness for learning, readiness can be developed with appropriate instruction. The concept of readiness for learning has a long history and diverse definitions. In this context, readiness is defined as the extent to which a student is prepared to learn in a given learning situation. Thus, the student's profile of learning strengths and weaknesses is used by teachers to design, customize, and adapt instruction

tailored to fit that profile in a manner that moves the student gradually toward independence.

A difference between differentiation practice and the traditional research-oriented search for ATI is that methods used to assess learning needs and establish profiles are often qualitative or captured informally by teacher observation and student work samples. ATI studies typically use quantitative indicators of aptitudes and outcomes, such as standardized assessments of ability or personality. When practitioners rely on informal assessments for differentiation, they need to have in-depth knowledge of their students—their cognitive and social strengths and weaknesses, their temperamental response tendencies, and other aptitudes—in order to gauge profiles with any accuracy. A pure approach to differentiation is seen as student-centered in the ideal, as individualized instruction matched to students' readiness to learn. But rarely is it practical for teachers to individualize instruction within a large classroom; so other forms of adaptive teaching have evolved, suggesting ways to create subgroups of students within classes with like profiles that should correspond to beneficial modes of instruction (Corno, 2008).

Recent Educational Trends Based on ATI Theory

Other trends in education and the learning sciences reflect the evolution of an ATI theory. Three important trends to emerge in recent years are Response to Intervention (or RtI), proficiency- or competency-based pathways (otherwise referred to as learning progressions), and data-driven instructional decision making (i.e., the need for teachers to use data and evidence to inform instructional decision making).

RtI focuses on identifying students who have displayed learning challenges and are at risk of failing. Its objective is to provide early interventions to those at risk through a feedback cycle of assessment, progress monitoring, and prescribed instructional interventions. The tight coupling of the feedback loop between performance/capacity assessment and instruction is a form of matching aptitude with appropriate instructional strategies. RtI comprises a tiered classification system with three levels. The first tier consists of instruction aimed at all students in a classroom or large group. The second tier focuses on instruction appropriate for small groups of students with similar specific difficulties or learning deficits (otherwise known as aptitude profiles). The third tier is individualization within the regular classroom setting. As with differentiation, for RtI to function effectively, teachers must prescribe and adapt instructional strategies to accommodate the learning of individuals as well as groups of students.

Proficiency-based or competency-based pathways is a somewhat recent approach in which students are viewed as progressing through a continuum or pathway of proficiencies or competencies at their own rate; some authors prefer to use the term *learning progressions*. The objective in all cases is for students to acquire deeper and more lasting knowledge (longer-term retention). For this to happen, however, there must be a level of individualization or customization in which the teacher aligns the instructional intervention to the needs of students and also adjusts that intervention and pacing according to students' evolving progress toward mastery or levels of specified proficiency (Sturgis, Patrick, & Pittenger, 2011).

Data-driven decision making for instruction has been a major emphasis of the U.S. education policy since the mid-2000s. It is premised on the observation that good teachers have always used a variety of data sources from students to inform their instructional planning (observed actions and interests, work samples, verbalizations, problem solving, test performance, etc.). Today's policymakers have articulated the importance of formalizing the collection of such data sources. They also recognize that educators should learn to produce "hard," or relatively objective, evidence to inform their decisions rather than rely on their instincts or informal experiences. A philosophical shift has occurred over the past decade supporting the need to use data to inform education practice, the different kinds of data that may be most appropriate, and the purposes for which those data are to be applied. The philosophical shift is away from data being used for accountability purposes (typically summative performance measures) toward data for continuous improvement. Data for improvement align more closely with informed instructional decision making. As with ATI theory, student data may be cognitive, affective, motivational, or behavioral. The more diagnostic the assessment and the tighter the chronological coupling, the more the instruction can be tailored to the needs of individuals or groups of students.

The essential component for data-driven instructional decisions is to align the right data to the decision-making situation; the data must fit the purpose of the decision. Furthermore, the greater the number and variety of data sources, the more informed

the decision will be. For example, state summative assessments cannot provide the kinds of information a teacher needs to make informed instructional decisions about specific students and their learning needs. These tests do not have the granularity or timeliness to actually inform instruction. Such data may provide a broad picture to a school or district for comparison purposes, but they cannot provide teachers with the deep knowledge of learner strengths and weaknesses needed to prescribe appropriate instructional remediation and inspiration to students across the spectrum of aptitude. Instead, a concatenation of different data from sources and indices, such as diagnostic and formative assessments, designed classroom performance activities and work samples, and semistructured observations, can help teachers capture and appropriately adjust instruction to each learner's profile of aptitude.

Despite the beliefs of some scholars, perhaps misled by what they viewed as inconsistent results reported in the handbook of Cronbach and Snow, ATI theory has evolved and remains foundational for various forms of contemporary studies in teaching, instruction, and the learning sciences. The concept of considering the aptitude profiles of individual students and adjusting instruction to match them can, as Snow liked to say, be traced back to ancient documents from the 5th century BCE; and yet it remains an essential part of current educational practice as well. Its fundamental principles resonate in the practices and policies of modern forms of adaptation such as those we have described. This legacy should not become lost history.

Aquinas and Thomism

Thomism refers to the philosophical positions and style of thinking to be found in the writings of St. Thomas Aquinas (1225–1274) and of those who are influenced by his manner of philosophizing and his substantive positions on philosophical issues. Thomism, or more accurately, neo-Thomism, is a variety of Thomist thought revived as a result of its official recommendation by Leo XIII in 1879 in an encyclical (papal document) titled *Aeterni Patris*. St. Thomas's system of thought and method of analysis are not, however, the exclusive preserve of those who seek to articulate and justify a Catholic philosophy of education. Thomism is also relevant to the work of philosophers who do not work within this tradition but who are prepared to engage in dialogue with it or who simply admire the cool rigor and relentless logic of Aquinas. For example, the spirit of his philosophy of education with its valorization of the life of reason and of careful argument can be found in the work of Harvey Siegel, a contemporary philosopher who is neither Catholic nor theist. The searching, analytic approach of Thomism and its substantive position on a wide range of issues can promote fruitful exchanges about the meaning and practice of education.

A brief bibliographical note is appropriate at this point. The major works of Aquinas include *Summa contra Gentiles*, *Summa Theologica*, and *De Veritate*; relevant sections from these texts can be found in Ralph McInerny's edited collection *Thomas Aquinas: Selected Writings* (1998). The philosophical positions adopted by Aquinas inform the papal encyclicals on education over the past century. In the 20th century, the French philosopher Jacques Maritain (1882–1973) was one of the most notable promoters of Thomism in the field of education, especially in his work *Education at the Crossroads*. As is clear from the short list of further readings at the end of this entry, Thomism has prompted much philosophical work relating to education over the years.

The next section of this entry deals with the general philosophical positions of Aquinas and draws largely on the *Summa Theologica*. This is followed by an overview of the implications of his philosophy for education. The third section deals with the Thomist theory of teaching and learning.

The Contours of the Philosophy of St. Thomas Aquinas

Aquinas affirms a view of human beings as part of a world that is made up of phenomena that possess objectively real natures. For Aquinas, the world has a reality that exists independently of how we perceive and understand it. He does not consider that knowledge consists in an inference from sensation; rather, he affirms the Scholastic adage that "nothing can be understood until it first appears to the senses" (*nihil in intellectu nisi quod pris fuerit in sensu*). He considers sense experience to be the starting point of knowledge and to be mediated via the intellect to constitute knowledge. Reality is thus amenable to the working of the human mind. According to the epistemology of Aquinas, the mind possesses an intuitive capacity to make the world intelligible and to attain truth.

Human beings are envisaged as rational creatures with powers that enable them to study the structure of reality, whose intelligibility is potentially susceptible of being disclosed by the exercise of their intellectual capacities. Rather than innate ideas, the mind contains the source of knowledge as a seed or germ that, at the very first contact with experience, has the power to conceive certain self-evident principles. Among these first principles, which become the bedrock of our thinking, are, for example, the notions of being or of the unity of being and the principle of causality. Virtue derives from the human capacity to grasp the ends to which human beings are naturally inclined, and the genesis of virtue is to be found in the apprehension of these ends.

Aquinas adopts the Aristotelian principle that all change is a passing from being potentially something to being actually that something. He also adopts the Aristotelian synthesis of the *four causes* and uses it to show what is necessarily involved in any development from A to B. The four causes explain the process. There must be (1) a *material cause*, answering the question "out of what"; (2) a *formal cause*, explaining the determining principle ("form") whereby we recognize the result of the change; (3) an *efficient cause*, answering the question of what effected the change; and (4) a *final cause*, the "purpose" or the "end" in terms of which the change came to pass.

According to Aquinas, a human being's highest dignity lies in her or his intellectual nature, where we find the image of God in its purest earthly form. The principal task of humankind is to think rationally and so to grow in knowledge. Accordingly, reason is human being's most important capacity, and the pursuit of truth is her or his primary and most fundamental duty. Aquinas sees love emanating from the pursuit of truth. The achievements of the will derive from the work of the intellect. For Aquinas, knowledge is not only a useful accomplishment, it is also valuable in its own right and worthy of being pursued for its own sake.

Deeply embedded in human nature is an urge to happiness in the form of a desire to achieve the goods that perfect the human being as a rational animal and especially as a social animal. This urge to be happy is a constant stimulus to action, but the ultimate impulse of human striving for happiness is to enjoy the beatific vision, that is, to participate in the life of God, where the ultimate perfection of humankind is to be found. Human striving is a search for this perfection and the cultivation of the excellence in thought and deed that leads to this state. The excellence envisaged by Aquinas represents a form of virtuosity that embraces moral virtue as well as accomplishment in all aspects of human life. Practical reason must provide guidance and judgment so that human beings may progress in all fields of human endeavor. God has given humankind many gifts to help people achieve a relative degree of excellence in these areas and to furnish them with a taste of what perfect happiness is to be like in the world to come.

After this brief overview of Thomist philosophy, the implications of this philosophy for education are explored in the sections that follow.

Aquinas, Thomism, and Education

So what then are the implications of the Thomist theory of knowledge for educational theory and philosophy? With its emphasis on clarity, rigor, and close, logical argument, the approach of St. Thomas is consistent with that of analytic philosophy as indeed is his confidence in the power of human reason. Yet Thomism differs from the latter in that it also offers a comprehensive philosophy of education based on an overarching conception of the nature and the purpose of human life that is underpinned by epistemological realism and an objectivist view of value. The analysis that is a feature of Thomist philosophy yields a metanarrative or grand theory, that is, a comprehensive or overarching account of the nature and purpose of human life and this is not, to be sure, a feature of the work of philosophers who work within the analytic tradition. Indeed, Thomism gives expression to the classic metanarrative of Western culture. Human beings are created by God to ultimately enjoy eternal life in his company. The *telos* or end of all teaching and learning is to enable human beings to attain this ultimate state of beatific perfection.

Here, something further must be said about Thomist teleology. This is the conception of the aim of education that has traditionally informed Catholic, and other religious, versions of education and schooling. The Thomist vision of the ends of education has even been invoked in the national context by the Irish State. This vision furnished the explicit underlying rationale for the primary school curriculum from 1971 to 1999 and was given expression in the document of the Irish Department of Education titled *Curraclam na Bunscoile: Lámhleabhar an Oide, Cuid 1* (*Primary School Curriculum: Teacher's Handbook*, Part 1, 1971):

> Each human being is created in God's image. He has a life to lead and a soul to be saved. Education is, therefore, concerned not only with life but with the purpose of life. And, since all men are equal in the eyes of God, each is entitled to an equal chance of obtaining optimum personal fulfilment. (p. 12)

This statement of the aims of education was challenged as infringing liberal principles and did not appear in the document published in 1999. The new document is based on the acceptance that, in a liberal democracy, it is not appropriate for a single substantive worldview to be taught as true in every school. Nevertheless, in a democratic state, proponents of a Thomist vision of education are not obliged to embrace the relativist position that all worldviews are equally valid. Yet considerations of liberal justice require they accept that differing versions of the good may be counted as reasonable, although a Thomist would deny that they are equally compelling.

More usually, a Thomist *telos* is to be found underpinning the education provided in Catholic schools. The traditional spirit of this *telos* is well described in the fiction/autobiography of, for example, James Joyce, Simone de Beauvoir, and Mary McCarthy. Yet the irony is that today many Catholic schools in many different countries are reluctant to

define themselves in terms of a Thomist *telos*. The uncompromising statement of aims reflected in the Irish document tends to be replaced by expressions of educational aims that amount to little more than a lowest common denominator of benign aspirations.

The Dynamics of Teaching and Learning

The educational vision of St. Thomas is based on the conviction that humankind has access to the truth about life and its purpose, but Thomist pedagogy is not at all dogmatic and didactic in the traditional sense of the teacher passing on authoritative truth to passive learners. His most extensive and well-known account of the teacher–learner relationship is to be found in *De Veritate* (Q. XI, a.1), but Ryan (2009) has disclosed sources of insight into the dynamics of this relationship in his earlier work. Concern to account for the activities of teaching and learning is actually a feature of Aquinas's work from his inaugural lecture on being appointed a *magister* or university teacher. Coincidentally, the task of giving an account of the relationship between teacher, subject matter, and learner was also one that the important analytical philosopher of education R. S. Peters wrestled with, and it has assumed a significant profile in contemporary philosophy of education with consideration being given to the complex conceptual geography of notions of discipleship, apprenticeship, imitation, and identification.

At this point, it is again necessary to make some observations about Aquinas's view on the place of God in teaching and learning. Aquinas believed that God was the animating impulse behind the whole universe, but this does not detract from the persuasiveness and subtlety of his account of the relationship between teacher and pupil in the educational context. Indeed, he explicitly rejects the view, defended by Saint Augustine in his text *De Magistro*, that only God can teach human beings and that, consequently, one person cannot truly be said to teach another. Augustine argues that, although human beings can indeed speak about truth, one person cannot teach another to embrace this truth because people learn not through the words of a teacher but rather through the action of God revealing truth in the soul via created things. For Augustine, teaching is the prerogative of God alone, and one human being can do no more than alert another to what she or he already knows. But, in his text on *De Magistro* in *De Veritate*, Aquinas emphatically rejects this view. According to the Thomist account, although God is ultimately the source of human knowledge and of the capacity to acquire this knowledge, it is perfectly reasonable to speak of one human being teaching another in the sense that one person can serve as the secondary cause of another's knowledge.

To understand how knowledge can pass from one person to another, Aquinas first considers how knowledge is acquired. As noted above, knowledge exists within human beings in the form of the seeds of elementary ideas, and accordingly, we can come to acquire knowledge without the intervention of teachers; this is called invention or discovery. If knowledge did not exist in an active rather than a passive way, then it would be impossible for someone to acquire knowledge by herself or himself. Therefore, an individual can serve both as a cause of her or his own learning as well as that of other people. A teacher, through *disciplina* (teaching), can trigger the movement from the potential that lies in the seeds of knowledge to actual knowledge. So how does this occur? This is a matter that Aquinas discusses both in the *De Magistro* section of *De Veritate* and also in two early texts that can be considered as part of his inaugural address on being appointed *magister*. These texts are known as *Rigans montes de superioribus suis* ("Watering the mountains from above, the earth will be filled with the fruit of your works," Psalm 10:13) and *Hic est liber mandatorum Dei* ("This is the book of the Commandments of God"; McInerny, 1998). So right from the outset, the reader gets a sense of the rich pedagogy of Aquinas as he draws on the resources of metaphor to explain the activities of teaching and learning. In this instance, he makes a comparison between water flowing from on high to assist in the ripening of fruit and the teacher bringing about learning in the student. The significant role exercised by the teacher in the imparting of knowledge is made further explicit in *De Magistro*, where Aquinas again has recourse to metaphor. The teacher points out to the learner the path of reasoning that she or he followed to reach her or his conclusions. The demonstrations used by the teacher could be described as tools or instruments to enable learners to understand something new. He compares the role of the teacher cooperating with the learner in communicating knowledge with the role of the doctor cooperating with nature in promoting the health of a sick person. Yet throughout the activity of teaching and learning, the ideas of the students are the basis on which all knowledge is constructed.

The teacher is a mediator of knowledge, but the primary source of this knowledge lies in the understanding of the learner. The teacher could therefore be described as one who builds on or shapes the learner's original mental construction of the world.

To conclude this section, it is important to note a comment in the first sentence of *Hic est liber mandatorum Dei*. This is a gloss on the words of Saint Augustine that themselves echo those of Cicero, enjoining the teacher to speak in order "to teach, to delight and to change; that is, to teach the ignorant, to delight the bored and to change the lazy" (McInerny, 1998, p. 5). The notion of changing highlights an integral feature of the educational philosophy of Aquinas. Knowledge and action are inextricably linked, and to say that someone knows something means that this knowledge informs the way she or he acts, a point that is echoed in the 20th century in the work of Gilbert Ryle. The implications for moral education are obvious because for a person to count as knowing how to behave means that she or he behaves in accordance with this knowledge. In a more general sense, for Aquinas knowledge is transformative because to count as knowing something the learner must internalize the knowledge, and this knowledge must inform the way she or he perceives the world. He disparages rote citation of authoritative answers because knowledge must come to life in the world of the learners. As Aquinas comments in *Quodlibet*, "If we resolve the problems posed by faith exclusively by means of authority, we will of course possess the truth—but in empty heads" (in Ryan, 2009, p. 92). Ryle's famous distinction between "knowing how" and "knowing that" is relevant here. "Knowing that" in the sense of being able to recite propositions does not count as an educationally significant achievement—learners must also demonstrate the "knowing how" necessary to fit what they have learned into an intelligible conceptual framework.

Conclusion

St. Thomas Aquinas was also very didactically aware, and his approach to teaching a text reflects a pedagogy that is as lucid and coherent as his philosophy. His approach to teaching a lesson is very structured and could indeed be commended to teachers at all levels in education. More generally, readers coming to his work for the first time will find in his approach echoes of analytic philosophy of the mid-20th century, of the close reading of texts to be found in the work of the New Criticism in poetry in the English-speaking world, and of the tradition of *explication de texte* in the French literary tradition.

For Aquinas, education is initiation into the life of reason that includes initiation into the life of virtue. He also was a committed Christian of deep and abiding faith, and his approach to philosophy and education is always informed by this faith that he conceives as entirely compatible with reason. His commitment to reason means his philosophy is not based on ideological assertion but rather on careful argument that is open to the challenge of those who hold opposing viewpoints. His philosophy of education can be said to derive from two principles: (1) commitment to clarity in reasoning and (2) openness to the force of the better argument.

Arendt, Hannah

Hannah Arendt (1906–1975) was one of the most influential political philosophers of the 20th century. Born in Germany to a Jewish family, she studied philosophy with Martin Heidegger at the University of Marburg. She was forced to emigrate when Adolf Hitler's National Socialist Party took power in 1933. After spending the next eight years in France, she immigrated to the United States in 1941, where she became a major part of a vibrant intellectual community. Arendt's major works—*The Origins of Totalitarianism* (1951), *The Human Condition* (1958), *On Revolution* (1963), and *Eichmann in Jerusalem* (1965)—dealt with philosophy, politics, and history.

Arendt wrote comparatively little about education and the philosophy of education. Apart from a couple of essays titled "What is Authority?" and "The Crisis in Education" in her book *Between Past and Future* (1977), she made relatively few references to this topic in her other works. However, a close reading of these two essays in the context of her major works suggests that Arendt's views on education developed out of two central threads in her thinking: (1) a traditional conception of authority and (2) her existential convictions. The result is a distinctively conservative approach to education, which she described in "The Crisis in Education":

> To avoid misunderstanding: it seems to me that conservatism in the sense of conservation, is of the essence of the educational activity, whose task is always to cherish and protect something—the child against the world, the world against the child, the new against the old, the old against the new. Even the comprehensive responsibility for the world that is thereby assumed implies, of course, a conservative attitude. (Arendt, 1977, p. 192)

Arendt's point is that adults need to preserve the world from the hands of the young, who might destroy parts of it if left to their own devices. To preserve this human world against the mortality of its creators means to constantly renew it so that it can provide a permanent home for succeeding generations who will inhabit it. This point is reminiscent of the mainstream conservative argument that holds that society and tradition are to be preserved by imparting to the young the worthy values and great ideas of the past. Yet Arendt also presents a stronger argument: that conservatism in education implies a willingness on the part of adults to protect the young from the world (i.e., from social conventions), which seeks to suppress the new and revolutionary in every child. Unlike mainstream conservative approaches that often ignore the fresh possibilities that newborns bring into the world, she insists that educators must cherish and foster them. For Arendt, perhaps the most important and difficult problem in education is how to preserve the new and revolutionary in the child while simultaneously conserving the world as a permanent home for human beings.

In Arendt's view, education involves a unique triadic relation among educators, the world, and our children, in which it is the educator's task to mediate between the latter two. Such a relation, she believes, is based on adults' authority and their desire to preserve both the world and the young. In education, it is precisely the authority relation and its corresponding conservative attitude that make room for renewal and innovation. Renewal and innovation are contingent on the young coming to know the world; only adults, because they are already familiar with the world, can teach children about it. Education, she argues, is worthwhile when the conservative and the revolutionary go hand in hand, when we preserve the past for the sake of the new:

> Exactly for the sake of what is new and revolutionary in every child, education must be conservative; it must preserve this newness and introduce it as a new thing into an old world, which, however revolutionary its actions may be, is always, from the standpoint of the next generation, superannuated and close to destruction. (Arendt, 1977, pp. 192–193)

This last point should be underscored on the grounds that Arendt is one of the few modern thinkers who insist that in education we must be conservative for the sake of the new. She is not arguing, as mainstream conservatives have, that children should be taught the great works of the past because of their important educational insights and relevance for our lives. Rather, she is claiming that the past and the relation of authority are essential to help children realize their potential for creating something new. Without being taught the classic works of tradition, children would not have the basic knowledge needed to change and renew the world. And without adults assuming responsibility for the common world and guiding the young in it, children would not have the security needed to operate adequately in a rapidly changing world. In Arendt's view, the most important goal of education is to help children become

familiar with the world and feel secure in it so that they may have a chance to be creative and attempt something new.

Yet what distinguishes Arendt's conception of educational authority is not merely the idea of preserving the past for the sake of the new. No less important is her emphasis on human action and the fact of natality on which action is ontologically based. Natality refers to the reality that each child has the potential to initiate something new in the world by virtue of the fact that "with each birth something uniquely new comes into the world" (Arendt, 1958, p. 178). The fact that birth constantly brings newcomers, who are not only beginners but also unique into our world, means that the unexpected can be expected from them. It means that the young can intervene in the ordinary course of events and initiate radical changes in society. According to this view, education should be aimed at preparing the young for a life of action—for a life of involvement in and transformation of the world:

> Education is the point at which we decide whether we love the world enough to assume responsibility for it and by the same token save it from the ruin which, except for renewal, except for the coming of the new and young, would be inevitable. And education, too, is where we decide whether we love our children enough not to expel them from our world and leave them to their own devices, nor to strike from their hands their chances of undertaking something new, something unforeseen by us, but to prepare them in advance for the task of renewing a common world. (Arendt, 1977, p. 196)

Thus, Arendt believes that education should be aimed at preparing the young for taking responsibility for the world. Yet this responsibility does not mean clinging to traditional morals or returning to a "golden past," as mainstream conservatives advocate. Rather, it means preparing our students for action, that is, for intervening in the world and creating a more humane society. Arendt thinks that education is ideally a space that can help students prepare for taking responsibility for the world by providing them with the kind of information and skills (e.g., moral reasoning) that they will need to become informed and engaged citizens in a democratic society.

ARISTOTLE

The educational ideas of the Greek philosopher Aristotle (384–322 BCE) have been widely influential across the ages but since the 1980s especially so with regard to moral and civic education, and flourishing as a goal of education. Aristotelian ideas about practical reason and friendship have also had considerable influence in philosophy of education. This influence has been not only facilitated by a wider revival of scholarly interest in Aristotle's philosophy but also shaped by the related emergence of the virtue ethics movement in moral theory and communitarian movement in political theory. This entry briefly reviews Aristotle's life and works and then discusses the central elements in his philosophy of education.

Life

Aristotle was born in the town of Stagira, in Chalcidice, between the Balkans and the Greek peninsula. His father, Nicomachus, was physician to the Macedonian court, a circumstance influential in Aristotle's own lifelong ties to it. At the age of 17, he began 20 years of study at Plato's Academy in Athens, until the latter's death in 348/347 BCE. Perhaps owing to political difficulties arising from his Macedonian connections, Aristotle then left Athens for Assos and Mytilene, where he is thought to have done much of the detailed fieldwork on which his biological works were based. At the invitation of Philip II of Macedon, he returned to Macedonia in 342 BCE where he was tutor to Philip's son, the

young Alexander the Great. Returning to Athens in 335 BCE, he founded his Peripatetic school or *Peripatos*, named after its site, the *peripatos* (probably a colonnaded walk) of the monumental public gymnasium at the Lyceum—a sanctuary established for the worship of Apollo the wolf slayer (*Lykeios*)—but already by the late 5th century, it became a place of leisure (*scholê*) and higher learning favored by Sophists, Socrates, and young men who came to exercise and listen. There he collaborated with colleagues in systematic research on an astounding array of topics; founded several disciplines, including zoology, logic, and political science; gathered a library of documents and research materials without precedent in the Greek world; invented scientific prose and oversaw its voluminous production; and led other members of the school in teaching students of diverse philosophical and family backgrounds. The death of Alexander in 323 unleashed anti-Macedonian feeling, which forced Aristotle to withdraw to his mother's estate in Chalcis. He died there in 322, leaving his library to Theophrastus and expressing a preference that the latter should succeed him as *scholarch* or head of the Peripatetic school.

Works

Aristotle's surviving writings are numerous and remarkably wide ranging, yet these are only a fraction of what he produced. A list of his writings compiled in the years after his death, when many were in use at the Lyceum and widely in Alexandria, include a history of Athenian dramatic performances, constitutional histories of 158 states (of which only the history of Athens has survived intact), and dialogues praised by Cicero (106–143 BCE) for their eloquence. The collection left by Theophrastus was brought to Rome after the fall of Athens in 86 BCE and was edited there between 70 and 20 BCE by the Peripatetic philosopher, Andronicus of Rhodes, who grouped many of the books (papyrus rolls) into treatises. This has served as the basis for all subsequent editions of Aristotle's works, and most of what Andronicus considered important has survived. It is widely accepted that the books comprising these surviving works are lectures or compilations of notes that Aristotle had not prepared for publication. The works form a deeply interconnected whole, but they are conventionally organized into distinct philosophical categories: *logic* or the "*Organon*" (works constituting the "instrument" or tools of philosophical inquiry); *metaphysics* (concerning being, substance, matter and form, etc.); *natural philosophy* or "physics" (concerning everything in the natural world, both inanimate and animate, hence everything from physics in the modern sense, to meteorology, the movement and parts of animals, and dreams); *political science* (comprising ethics and "legislative science"); *rhetoric*; and *poetics*.

It is principally in his *Nicomachean Ethics* and *Politics*, works which present themselves as an ordered pair comprising political science (*hê politikê epistêmê*), that Aristotle addresses education, though even in these works, the direct remarks about education are brief except in the final book (VIII) of the *Politics*. His purpose there is to argue that schooling should be publicly provided and the same for all citizens and to provide a general account of the aim and content of such schooling. There is no sustained discussion of higher education in the extant works, but important features of Aristotle's conception of it can be inferred from scattered passages in his works and from independent testimony concerning the practices of his school.

The Idea of a "Universal" Education

Aristotle says in *Politics VIII* that the primary concern of education is to cultivate a capacity to form good or correct judgments and (what is closely related so far as *moral* judgments are concerned) a disposition to take pleasure in admirable human dispositions and actions. His work, *On the Parts of Animals*, opens similarly with the claim that to be educated is to be able to form a sound judgment of an investigation or exposition, a person of "universal" education being one who is able to do this in all or nearly all domains of knowledge. The ability to make sound judgments for oneself is a defining aim that unifies education at all levels, but *Politics VIII* is concerned with a stage of education in which the development of good judgment is strongly linked to the formation of moral dispositions, whereas *Parts of Animals I* is concerned with the principles by which the soundness of inquiries and expositions in a domain of higher learning (zoology) might be judged—principles Aristotle had devised and was in that very lecture preparing to impart. He evidently believed that to be educated in a field of study is to master its principles of inquiry and to be able to make sound judgments for oneself of matters within its sphere of competence. He furthered such mastery and ability in zoology and other sciences not only by focusing his students' attention on the principles

but also by encouraging involvement in investigations. Unlike Isocrates's school of rhetoric, in which a solitary master dispensed instruction to students for a fee, the *Peripatos* was an informal community of "friends" (*philoi*) engaged—in varying proportions—in research, instruction, and learning, without fees or contractual obligations. The collaborative nature of research in this setting is consistent with Aristotle's remark at the opening of *Metaphysics II*, that everyone has the capacity to contribute something to finding the truth, while no one can succeed adequately except as part of a larger, collective effort.

The students who heard the lectures constituting Aristotle's *Nicomachean Ethics* were told similarly at the outset that their experience of human conduct and familiarity with ethical facts would provide the starting points for a process of inquiry culminating in a systematic, reasoned body of ethical knowledge (*epistêmê*)—the ethical *knowledge* required for *phronêsis* (practical wisdom or excellence in judging what to do). Aristotle announces his practical philosophy as a science and a field of higher learning, and here, as in other educational domains, the overarching aim is the development of a form of good judgment.

Aristotle's understanding of the basis for sound judgment in a domain of knowledge is closely related to his conception of a science (*epistêmê*) as consisting of a structure of "first principles" and theorems derived from those principles, the first principles being necessary and defining truths of the natures of things in the domain. Understanding (*nous*) of first principles must begin in perception and memory of particular objects (*particulars*) and proceed through a unification of memories to general or universal suppositions about similar objects and, finally, analysis of *universals* or clear understandings of a common nature or essence. Grasping a science's first principles and what follows from them enables one to understand the causes of things in the domain.

Aristotle remarks at the opening of *Metaphysics I* that such understanding or knowledge is required to teach any art (*technê*, or craft), and the teaching of any science or art will naturally aim to cultivate such understanding or knowledge. An obvious consequence of his view that understanding and knowledge are rooted in perception is that teaching must build on or provide experience of relevant objects. What he emphasizes, however, is that experience or knowledge of individual objects is only a first step toward the grasp of universals and grasp of inferential and explanatory relations essential to scientific knowledge and the mastery of any art. A "manual" worker may learn by experience or guidance from a master yet lack the master's scientific or theoretical understanding, and for that reason be unable to rely on his own judgment and achieve consistent success in the variety of circumstances that arise.

Aristotle did much to advance this ideal of "universal" sound judgment or wisdom both personally and through the activities of his Peripatetic school, but the relationships between this ideal and the educational aims referred to in *Politics VIII* are not entirely clear. These aims pertain to the roles of the virtues, including theoretical wisdom (*sophia*) and practical wisdom (*phronêsis*), in flourishing lives and just political communities. It is not clear that either of these forms of intellectual virtue requires mastery of *all* domains of knowledge.

Liberal Versus Illiberal Education

Aristotle says in *Politics VIII* that education is not a preparation for paid employment, but for leisure devoted to intellectual activity. Greek education in *gymnastikê* (athletics) and *musikê* (music, poetry, and narratives—the "Arts of the Muses") was from the beginning a preparation for leisure, and it had remained so in large measure with the introduction of group lessons, but Aristotle (largely following Plato) reinterpreted this education as preparatory to the particular use of leisure he thought most admirable and satisfying. He allows that children should be taught useful things that are truly necessary (referring to reading and writing, gymnastic exercises, and drawing), but not so much of these useful things as to interfere with the development and exercise of virtues (*arête*, excellence, and goodness)—the virtues of thought no less than moral virtues. Dividing occupations and arts into the *liberal* (*eleutherios*, free) and the *illiberal* (*aneleutherios*, unfree), he advocates teaching the former only, and doing so only to a *degree* consistent with the exercise of virtue and with the *object* of cultivating the virtues foundational to living well and happily. Education in musical performance is defended at some length as liberal insofar as (a) the music contributes to moral development by imitating good character and producing delight in its apprehension, (b) the resulting appreciation of what is good provides the basis for good *judgment of* musical performances later in life, and (c) the selection of instruments and mode of

instruction aim at the student's own "improvement" and not to please an audience with feats of virtuosity, as a paid performer would be expected to do.

Like other 4th-century writers, Aristotle treats what is *illiberal* or not free as synonymous with what is "banausic." The Greek term *banausos* designates an artisan whose work is "manual" or involves use of the hands, but it is pejorative and expressive of the prejudices of a leisured elite in implying subservient catering to others through commercial exchange, hence a kind of dependence or lack of freedom. Beyond such dependence, all paid employments are "banausic" and illiberal according to Aristotle, because they "absorb" and "degrade" the mind (undermining the freedom to guide oneself by one's own good judgment). In conceiving of a public system of day schools in which all citizen children receive the same education together, yet receive no education preparatory to paid employment, Aristotle has in mind a society in which citizens are primarily land owners who manage their farming households but are not personally engaged in the manual labor of farming.

We should be able to use leisure well, Aristotle says, and there are branches of learning that should be valued for themselves and studied with a view to spending leisure in intellectual activity. He refers to music as providing intellectual enjoyment in leisure and seems to regard it as providing occasion for the contemplation of human goodness and beauty, but the branches of learning he has in mind are more generally ones in which theoretical wisdom or *sophia*, the highest human virtue, is exercised in *theoria* or contemplation of the best or "most estimable" objects of knowledge. "Best" may mean divine, and human excellence may qualify as divine, but the musical inducement of contemplation of such excellence would not constitute an exercise of *sophia* without a grasp of the universals of human goodness grounded in ethical science.

Aristotle argues in *Nicomachean Ethics I* and *X* and *Politics VII* that the happiest life for a human being is one that makes theoretical contemplation its highest end. A person might have a happy life by devoting himself to political affairs, engaging in activity that suitably exhibits the virtue of *phronêsis*, but the life devoted to intellectual activity exhibiting the virtue of *sophia* is happiest and complete in itself. Happiness or *eudaimonia* is a human being's natural highest end, and the activity of politics—a *productive art* (*technê*) aiming at something beyond itself—cannot qualify as a highest or ultimate end, Aristotle argues. The view that emerges is that a liberal education should be valued as a direct contribution to human flourishing; it prepares students to engage in intellectual activity that is inherently admirable and rewarding, activity that expresses or constitutes human flourishing or *eudaimonia*.

Aristotle regards moral virtue as an *internal* psychic requirement of a happy life, and his reason for doing so is important to understanding the progression of education from moral habituation to the exercise of wisdom essential to a happy life. According to the *unity of virtue* doctrine elaborated in *Nicomachean Ethics VI*, sound judgment both presupposes and completes the moral virtues; no one can develop sound judgment without first possessing natural or habituated forms of all the moral virtues, and no moral virtue becomes a *true* virtue unless habituation through guided practice is followed by teaching that leads to sound judgment. A happy life is occupied with the most suitable exercise of *sophia* or *phronêsis* and, therefore, requires the possession of sound judgment. Sound judgment is only possible if one perceives the world accurately in its various ethical aspects, and it is what we do and practice that shapes the cluster of dispositions that constitutes a habituated moral virtue—what we desire, take pleasure in, and *perceive* as good.

Education, Justice, and the Human Good

Aristotle begins from the idea that all human beings desire to live well or happily, and he conceives of a just society as one that is designed to enable everyone to live well. Believing he has shown that the life that makes theoretical contemplation its highest end is the uniquely best life for human beings, he holds that a *polis* (politically autonomous city) is properly a partnership in living this *best* kind of life. The *polis* described in *Politics VII* and assumed in *Politics VIII* is the one Aristotle says is the best that is possible in highly favorable circumstances, a city in which every (free, male) citizen possesses true virtue and cooperates with others in leading a flourishing life. (Aristotle says at one point that women, being half the citizens, should be educated, but he offers no specifics, and there are only references to sons and boys being educated in *Politics VIII*.) The *Politics* offers not only ideals and best possible arrangements but also a conception of the most just arrangements feasible for most societies and systematic guidance for improving all kinds of regimes. A clear message in this is that any society that aspires to be just will

endeavor to provide its citizens with what they need in order to live well and cannot provide themselves, notably, the education foundational to living well.

Politics VIII opens by observing that education should be of paramount concern, and the same education should be provided to "all" through a public system, not only because the city has one common end (living the best life), and the fulfillment of this end through activity expressing virtue requires prior "education and habituation," but also because it matters to the quality of the constitution (how a society functions as a political community). Because the best constitution achievable by most societies is institutionally a stable, consensual rule of law providing representation and powers to all classes, and one that is dominated by a large middle class in a way that prevents polarization and encourages cooperation, education serving the quality of the constitution would promote equality, civic friendship, and the moral and intellectual virtues essential to productive participation in collective self-governance. Education serving just civic purposes in such ways remains *liberal*, because the virtues of citizenship that are inculcated are no different in kind from those any human being needs to live well, and cooperating in collective self-governance is not servile.

Arnold, Matthew

Matthew Arnold (1822–1888) was among the most important public intellectuals in 19th-century England. A renowned poet, he held the post of Oxford Professor of Poetry and was a preeminent cultural critic of the time, one whose works continue to be read today. It is less well known that he was also an educational reformer with wide practical experience as an inspector of schools and author of official reports on foreign education. Arnold's theory of education centers on the idea that "culture" must be regarded as the normative social value and that acquisition of culture must be extended across class divisions by state-supported schools. In the long debate between proponents of science-based and literature-centered education, Arnold was a leading voice for the value of the humanities. A theorist of high culture and liberal arts education, Arnold at the same time advocated egalitarian, modern schooling for the nation. His ideas remain contentious in current debates over cultural theory and education. Because both his philosophical and practical interests in education begin with the idea of culture, in a nonanthropological sense, it is important to grasp his understanding of the term.

Culture

Arnold's most widely read volume is titled *Culture and Anarchy* (1869/1994). In it, he argues that without "culture" 19th-century social transformations in class relations, economic distribution, and social status will inevitably lead England into "anarchy." Although he rarely defines a term without using concepts that themselves require definition, Arnold means by *culture* the knowledge, understanding, sensitivity, and good taste that comes from

the elite, classical education provided by the great public (i.e., private) schools like Eton and Harrow and thereafter by the Oxbridge universities. But culture is not exclusively the province of the privileged. In his familiar words, culture is the quality of "sweetness and light." It is the critical ability to "see things as they really are," and it derives from sustained exposure to the "best that has been thought and said." Culture is the quality of an educated and cultivated mind that connects present ideas to those that have gone before, an inner, dynamic growing of mind and spirit toward greater "perfection." Arnold saw the opposite of culture in his age's faith in what Thomas Carlyle, his near contemporary, called "machinery": the utilitarian devotion to material goods and aspirations. Against this tendency of his day, Arnold called for the expansion of culture, or sweetness and light, into the worlds of commerce, politics, economics, literature, art, and education.

Class

Like Thomas Carlyle and John Stuart Mill, Arnold addressed the central issue of his time: the form English society would take in a period of dramatic change. The ascendancy of the middle classes over the rule of the aristocracy and the agitation of the lower classes for industrial regulation and democratic participation left traditional social and political structures unsettled. Arnold's analysis broke the social classes into three groups, each of which occupied a cultural and educational niche. At the top of the social hierarchy was the aristocracy, whom he called the "barbarians." Staunchly individualistic, with an educated "exterior culture" of refined behavior and tastes, at their best, they represented the conduit for genuine culture; at their worst, they were indolent and self-indulgent. The other end of the social spectrum was occupied by the "populace," or laboring classes. Poorly educated and without culture, as Arnold defines it, they were a social and political challenge for the democratizing country. But Arnold's attention was primarily focused on the education of the middle classes, whom he called the "Philistines." Including professionals, financial people, manufacturers, shop owners, clerks, and civil servants, who were living "dismal and illiberal" lives, this class was perversely resistant to light. To him, the middle classes were so immersed in the material world of success, acquisition, and advancement ("machinery") that they could not apprehend the value of culture. They therefore had little capacity for the kind of leadership that could benefit the nation, and in fact, they might be a danger to it. This rising ruling class had to be enabled to make judgments based on the "best that has been thought and said."

Education

Arnold traveled the country as inspector of elementary schools and knew firsthand the condition of education in the nation; he was especially interested in creating a system of state schools for the middle classes. If the workers were to rise into a ruling middle class, there had to be a system of state-established secondary schools to ensure a "civilized middle class to rise into." Education at the great public schools was generally reserved for the gentry and aristocracy, and only a few of the top middle-class families were admitted. But the rest of that class, he said, were the "worst schooled" in Europe. Even where he found education, it consisted mostly of information devoted to the purposes of commercial and material utility. He proposed to remedy those deficits, especially the lack of humanizing ideas, culture, and moral ideals, by turning to France's example: a national system of state schools that kept costs moderate while providing a good education to the middle classes. These schools, as Arnold envisioned them in England, would provide students access to what is "really human." They would link the middle classes to the best culture of their nation, connect them to the great institutions of learning, and "fuse" them with the classes above, creating a common culture. The educational rapprochement between the classes would provide students contact with higher standards, preserving the middle class from a vulgar tendency to overrate their "inferior" culture. Finally, impartial state schools would reduce sectarianism in education. State secondary schools, in other words, could remove those liabilities that, to Arnold, made middle-class ascendency a danger.

Curriculum: Science Versus Literature

For several decades after the middle of the century, a vigorous debate ensued over the question of whether a science curriculum or the study of literature should be central to school reform. The foremost apostle of culture, Arnold, was attacked for denigrating instruction in the sciences and for advocating an outdated classical, belles lettres curriculum. Among his critics, Charles Darwin's defender, Thomas Huxley, acknowledged that Arnold was not entirely

opposed to science education but maintained that he accorded too much privilege to literary studies. Arnold responded that a basic knowledge of science was necessary but insufficient. It is human nature, he argued, to want to connect knowledge with our own conduct and appreciation of beauty, with our moral understanding and aesthetic sensibilities. Science cannot provide this connection, while literature, or the humane letters, from all ages of human history can engage the heart, refreshing, fortifying, and elevating us. It is only poetry that can "interpret life for us."

Making accessible civilization's best interpretations of life is to Arnold the task of the discerning "critic." The critic, setting aside all practical and transient considerations, assesses cultural value on the basis of great works that serve as "touchstones," or standards, for evaluating other works. Education acculturates the young to those standards, aligning judgment with established values. Arnold's educational theory is a part of his larger social criticism: Normative culture, spread by education and maintained by evaluative criticism, preserves the identity and cohesion of the nation and stabilizes its class structures.

Critics and Legacy

Arnold's ideas encountered spirited response. One of his most skeptical contemporary critics, Frederic Harrison, charged that the problem with Arnoldian culture was that it stood aloof from the misery of the world, and the view of Arnold as removed from the raw conditions of English life was common. Other critics commented on his refusal to define and specify terms, on his lack of attention to practical politics, and on his turning to the Continent for ideas and models. Skeptics notwithstanding, Arnold takes his place in a lineage of criticism beginning with Samuel Coleridge, William Wordsworth, and Thomas Carlyle and continuing with T. S. Eliot's "The Modern Element in Literature," F. R. Leavis's *The Great Tradition*, Mortimer Adler's "Great Books" curriculum, Lionel Trilling's liberalist criticism, E. D. Hirsch's search for a common culture, and the core knowledge movement in schools. In recent cultural politics, these generally represent ideologically conservative positions. Cultural criticisms from further left take exception to Arnold on the grounds that his idea of culture represents the hegemonic elitism of middle-class liberals. The Marxist critic Terry Eagleton charges Arnold with the erroneous historicism of regarding a class ideology as a legitimate worldview. Postcolonial critic Edward Said argues that Arnoldian values constitute a link in a chain binding one group together while banishing the outsider. However it is viewed, Arnold's "culture" remains a point of contention in critical debates over educational theory and cultural politics.

ASSIMILATION

Assimilation, in common parlance, refers to a unidirectional and linear process that occurs when one group assumes the dress, speech patterns, tastes, attitudes, and, perhaps, most important, the economic status of the dominant group. However, in recent years, this perspective has been challenged. Newer theories of assimilation highlight the impact of structural- and individual-level factors and different outcomes for assimilation among immigrant and host groups.

Classic Assimilation: Robert Park and the Melting Pot

The earliest version of the assimilation model is that of classic assimilation. The key assumption of this perspective is that there is a gradual but natural process by which diverse ethnic groups come to share

a common culture. Assimilation, however, is seen as a subtractive process in which immigrants lose ethnic/national characteristics to be absorbed into the dominant mainstream culture. From this viewpoint, it is the dominant group that sets the terms of what it means to be assimilated. The process is deemed irreversible but also considered to be extremely beneficial to the newly assimilated immigrants.

The sociologist Robert Park was one of the first researchers of immigrant communities in the United States in the 1920s (and a Jewish immigrant himself). Park is responsible for two key ideas within the classic assimilation camp: (1) the melting pot metaphor and (2) the concept of marginal men.

Park (1928) believed that every society was to some degree a successful melting pot where diverse populations were merged, acculturated, and eventually assimilated, albeit at different ranges and in different ways. He proposed a four-stage "race relations cycle" that began with contact and moved into competition (in terms of both economics and new social organization). The third stage suggested a period of accommodation, but ultimately, men and women would assimilate into the dominant group—the final stage of the cycle. This is from where the "melting pot" metaphor arises.

Despite this straight-line assimilation trajectory, Park maintained that immigrants were often "marginal" men and women; that is, they found themselves between two cultures. For Park, marginality implied conflict not only between cultures but also between social innovation and cultural sophistication. Compared with the "indigenous" person, the marginal person according to Park was "the individual with the keener intelligence, the wider horizon, and the more detached and rational viewpoint" (Park, in Stonequist, 1937/1965, pp. xvii–xviii). However, it is the more negative aspect of marginality that has dominated the immigration debate, in great part due to the work of Park's student, Everett Stonequist.

Stonequist (1937) further elaborated on Park's "marginal man" with the description of the "marginal personality," which he argued was evident in individuals who were initiated into two or more historic traditions, languages, political loyalties, moral codes, or religions. This "marginality" between two static cultures was viewed as a problem, a source of anxiety, and a weakness that needed to be overcome. This seemingly commonsense notion that saw marginality as a state of uncertainty and conflict has been used as a source of support for subtractive assimilation policies.

The New Assimilation: Richard Alba and Victor Nee

The influx of non-European immigrants led to the questioning of the classic assimilation model. The passage of the 1965 Immigration and Nationality Act of 1965 (the Hart-Celler Act), which prohibited the exclusion of immigration and naturalization on the basis of race, sex, or nationality, opened the doors to many non-European (read non-White) immigrants to the United States. Despite this demographic shift in immigration, Richard Alba and Victor Nee argue that assimilation has been, and will continue to be, the "master trend" for newcomers and their descendants. They acknowledge that a degree of racism and ethnocentrism will always be part of the American fabric, and that there are immigrant pathways other than to assimilation, yet they believe that the classic assimilation model still remains valid. The evidence for this claim is that newcomers—irrespective of their race or ethnicity—change their language and culture as they gain contact with mainstream society; at the same time, the mainstream society increasingly accepts more diversity. Thus, they acknowledge that the mainstream itself is changed by immigration, eliminating the one-sided and normative assumption that only the newcomers change. Yet Alba and Nee do not assume assimilation's inevitability or even its desirability as a strategy in the eyes of newcomers. Rather, assimilation may be either a conscious strategy or an "unintended consequence" resulting from everyday decisions. They argue that immigrants should be allowed to assimilate at their own pace and in pursuit of their own interests. In brief, assimilation continues to be the dominant trend in American society, although its outcome may be uneven.

Critiques and Alternatives to Classic Assimilation

Classic assimilation theory has worked relatively well in explaining the assimilation trajectories of European immigrants to the United States. However, it remains embedded in binary oppositions (e.g., us/them, citizen/noncitizen, resident/"alien," legal/illegal, ethnic/nonethnic). This has the effect of excluding or "othering" certain groups. Referring particularly to the "new-assimilation" model, critics argue that for non-White immigrants, high levels of acculturation have not created the deep sense of belonging that has emerged for White ethnic immigrants. Straight-line assimilation also ignores

the other outcomes for immigrants, such as that of isolation, which occurs when a group willingly or unwillingly segregates or disconnects itself from the dominant culture. Consequently, its application to more recent non-European immigrant groups has met with challenges and given rise to alternative theories of immigration.

Margaret A. Gibson's Additive Acculturation

Classic assimilation ignores the *possibility* that immigrants may assume composite or dual identities such as Pakistani American, German American, and so on. This phenomenon is what Gibson (2005) refers to as "additive acculturation" or "accommodation without assimilation" (p. 582). It allows groups to preserve their identity in matters of religion, culture, language, and heritage while, simultaneously, encouraging full participation in the country's political arena.

Segmented Assimilation and the Rainbow Underclass: Alejandro Portes and Ming Zhou

The segmented assimilation perspective, advanced by Alejandro Portes and Ming Zhou (1993), argues that while assimilation continues to serve as a norm for immigrant adaptation, its outcomes have become segmented. That is, immigrants are either confined to "permanent underclass memberships" or experience rapid economic advancement even as they intentionally preserve their immigrant community's values and solidarity. The main contribution of Portes and Zhou is their focus on what factors influence the outcomes for immigrants. These include individual-level factors, such as parent–child relationships, and also contextual factors, such as racial discrimination, urban subcultures, and labor market prospects.

The Pluralist Perspective

By recognizing the impact that various groups have made on American society, the pluralist perspective breaks away from the "us/them" binary and instead provides a fresh way to look at what it means to be American. It thus challenges the passive, unconscious individualism of the assimilation model by postulating a more active role on the part of immigrant groups in defining their identities and solidarities. Moreover, it acknowledges that this process of negotiation is not just between the majority and minority groups but also among minority groups and even within groups themselves. The pluralist perspective is not without its shortcomings; major criticisms are that it overlooks how structures impede the integration process and that it fails to give credence to issues pertaining to the second generation.

ASSOCIATIONISM

How we (humans and animals) acquire knowledge through learning has been thought to involve the process of associating—a psychological activity whereby one thing is connected with another. Accounts of how this occurs have been provided through the doctrine of associationism, one of the oldest and most influential theories of how the mind works. Associationism attempts to explain what exactly connects with what and the conditions necessary for the connecting to occur.

An embryonic account of associationism first appeared in Aristotle's *Memory and Reminiscence*. He proposed that remembering begins with an

intuition that is either similar to, contrary to, or occurring close in time to (contiguous with) the idea we seek to remember. This conception of memory dominated until the 17th century when a more developed theory of associationism began to emerge via the British empiricists (Thomas Hobbes, John Locke, and later, George Berkeley, David Hume, and others). It attempted to account for all mental phenomena and became the basis of British empiricist epistemology. The theory had four general features:

1. *Elementarism:* Complex psychological configurations are constructed or built up from simple elements such as ideas, perceptions, or impressions.
2. *Sensationalism:* The simple elements have their basis in sensory experience.
3. *Connectionism:* The simple elements are connected or associated together through experience to form complex configurations.
4. *Laws of association:* Certain conditions must be experienced for the associating to occur.

Differences between the British empiricists were minor. With regard to the laws of association, most accepted the conditions *resemblance* and *contiguity*—that is, when two ideas are similar or are frequently experienced together and one idea is subsequently activated, so is the other. Classical associationism culminated in the mid-19th century with John Stuart Mills's thesis that, in some cases, the associative whole is qualitatively different from the sum of its parts.

Toward the end of the 19th century, an important shift in associative theory occurred in America. Edward L. Thorndike's research into animal behavior led him to conclude that the association is not between ideas (animals do not possess any ideas) but between an antecedent stimulus (a sense impression) and what the animal does in response. Associations, or connections, were strengthened by use and weakened by disuse (the law of exercise), and the strength of the connection between stimulus and response was also enhanced if the desired response was rewarded (the law of effect). In *The Principles of Teaching*, Thorndike wrote that applying the law of association meant that teachers should put together what they wish to go together, keep apart what they wish to keep separate, and create a satisfying outcome by rewarding good impulses.

Thorndike's research was contemporaneous with Ivan Pavlov's demonstration that through repeated exposure to the sound of a bell before the arrival of food, dogs would eventually salivate in response to the bell; in other words, an association reliably occurred between the animal's experience of a conditioned stimulus (the sound of the bell) and its conditioned response (salivation before the presentation of food). Here, repetition and contiguity were the two conditions judged necessary for associations to form.

Thorndike's and Pavlov's research underpinned the substantial attention given to behaviorism (the theory that both human and animal behavior can be explained by observable processes such as conditioning, without appeal to inner or mental phenomena such as thoughts and feelings) during the first half of the 20th century. Hazy divisions emerged between those who thought that response–reinforcement associations were necessary for learning, those who explained learning solely through associative contiguity between the stimulus and response, and those who presumed that both were fundamental. In the hands of behaviorists, associationism was no longer a structural theory of the mind but a theory of learning and behavioral change. It was not ideas that were "glued together" but their observable analogues—stimuli, responses, and reinforcements.

Notwithstanding the prominence of behaviorism, experimental research into the formation of mental associations progressed, in Europe especially. This saw the beginnings of a sustained critique of associationism, albeit from very different quarters. Gestalt psychologists argued that the study of how associations are formed to generate action misses the point. Our perceiving, thinking, and learning is of complex wholes, not elementary components, and how we organize these wholes determines what we perceive.

Some philosophers held not only that elementarism is false but also that (1) the terms *mind*, *perception*, *impression*, *sensation*, *idea*, *memory*, *mental representation*, and so on cannot refer to mental entities because the psychological is relational—it is about processes or events occurring over time, not relatively static representational items internal to the mind or the brain, and (2) even if these mental items were not reified fictions, they could not be the immediate objects of awareness because this leads to a solipsism that has the subject never apprehending anything other than its own internal representations. In short, complexity and relatedness are to be discovered by directly apprehending reality—they

cannot be constructed by a mind (or a brain) that associates data of a less-than-complex kind.

Others bypassed these fundamental criticisms and targeted associative accounts of *how* we come to learn and remember. When the cognitive "revolution" manifested in the mid-1950s, it did so, in part, because associative learning theories were judged to be either limited in scope or plainly false. Noam Chomsky, for example, argued that stimulus–response associations alone could not explain language learning. John R. Anderson and Gordon Bower maintained that such associations could not account for the complexity of human memory. And, neglecting the critique of mental representationism above, they developed a "neo-associationist" theory that advanced an internal mental architecture involving representational networks of "trees" that consisted of linked (associated) "memory nodes."

More recently, artificial neural networks of linked nodes (which purportedly model the brain) have been developed to "learn" cognitive tasks such as face recognition and the detection of simple grammatical structures. They are yet to master the systematicity of "higher" cognitive abilities, and this limitation has been the subject of Jerry Fodor's polemic against associationism—the theory cannot account for our ability to reason or our ability to entertain thoughts with semantically related content, for example, anyone understanding the sentence "Tom likes Jenni" will also understand the sentence "Jenni likes Tom." Associative learning theory has also been denounced for assuming that the temporal pairing of two stimuli, for example, a noise and a shock, constitutes a single trial and that this temporal pairing is critical for association formation. These assumptions are said to lack ecological validity because the flux of life is multidimensional, not a series of discrete trials.

These criticisms aside, contemporary neuroscience maintains that learning involves the strengthening of connections between neurons (changing neuronal connectivity) across the many "cortical association areas." Repetition, therefore, supports learning, while the absence of repetition and exposure results in its decay. And although the role of associationism in explaining cognition has been weakened, in practice Thorndike's directions to teachers are difficult to escape. Contiguity, repetition, and reinforcement remain key principles in designing a learning environment.

At-Risk Children

Risks are factors that increase the likelihood of negative child development, behaviors, experiences, and outcomes. Risks also reduce the probability of positive child development. In general, the more risks experienced by children, the poorer is their development. Risks can occur at the level of the individual, the family, or the community, but often, they occur at all three levels. Moreover, children and youth who experience risk in one setting are more likely to experience risk in other settings as well. Risks can be distinguished from protective factors, which help insulate children from negative developmental influences. Risks are also distinct from promotive factors, which foster positive development. While practitioners and advocates, as well as researchers, increasingly emphasize positive outcomes and factors that promote positive outcomes, it is clear that minimizing risks can improve the prospects for children and families. Intervention programs that reduce relevant risks can have significant effects on the development and well-being of children and youth. This entry discusses the types of risks that affect child development; how risks are defined at the level of the child, the family, and the community; and how risks affecting child development are assessed. Risks are relevant to the philosophy of education both because the well-being of children is intrinsically valuable and because the risks experienced by children affect their ability to be productive as adults.

Types of Risks and Outcomes

Developmental outcomes for children and youth fall into the domains of physical health, mental health, cognitive development and educational achievement, and social development and behavior. Some types of risks are more relevant for one domain than another. For example, inadequate nutrition can have effects particularly on physical health and cognitive development, while low literacy among caregivers may particularly affect children's educational achievement. However, development in one domain frequently affects development in other domains. Accordingly, it can be anticipated that risks may have broad and even pervasive implications for child and youth development.

Risks can affect children directly or indirectly. Thus, for example, a child or youth may be directly victimized by crime or violence. Alternatively, he or she may be affected indirectly because children are not allowed outside in neighborhoods where crime and violence are pervasive, which can reduce physical fitness and increase obesity. And of course, risks vary in their intensity. Experiencing abuse or neglect is likely to undermine children's development much more than their living in crowded housing.

Risks also vary in the extent to which they are malleable. The education or marital status of a parent may not be easily affected by programs or policies. On the other hand, parents' practices related to child safety or family diet may be subject to change.

Risk Levels: Child, Family, and Community

As noted previously, risks can be identified at the level of the child, the family, or the larger community. Child-level risks can include health problems, difficulties with learning, mental illness, possession of a difficult temperament, or a physical limitation. While one can object to the notion that children can pose a risk to themselves, it is the case that some child characteristics can undermine their prospects for positive development, through no fault of the child. For example, a child who experienced a poor intrauterine environment and premature birth has an elevated risk for negative outcomes from day one. Identifying such risks can and should stimulate early intervention.

Community-Level Risks

Living in a violent or war-torn community poses obvious risks to children's survival and development, but the range of potential risks in a community is broader and more subtle. Risks may be environmental, such as high levels of air pollution and/or mistrust in the neighborhood, a lack of services such as transportation and playgrounds, and/or presence of lead in housing materials or water systems. Alternatively, risks may reflect a lack of cohesion and support among members of a community.

Family-Level Risks

Families are central to the development of children. Accordingly, risks at this level can have devastating effects. Family-level risks come in varied forms. One type is economic—families may lack the income to provide adequate food, housing, and clothing, as well as the books and experiences that children need to develop optimally.

Another type of family risk can come in the form of parenting practices. Parents may engage in harmful behaviors, such as hitting and screaming or smoking in the home around their child. Alternatively, parents may not provide sufficient positive parenting, such as speaking with or reading to their child. In addition, the absence of parental engagement can pose a risk. For example, parents may fail to guide a child's eating habits or moral development, perhaps because of depression, because they are focused on work or other responsibilities, or because they are simply busy with adult activities.

Parents may also fail to provide good role models. Parents can and do often model positive behavior, such as volunteering, exercising, or being a careful driver. However, parents can also model very negative behaviors. For example, parents may fight, cheat, use drugs, or follow unhealthy diets. Even if their behavior is not directed at the child, children can often still observe the behavior or its consequences (e.g., a hangover); such negative role models can undermine their positive development.

Unfortunately, risks tend to co-occur: Children and youth exposed to one type of risk are often exposed to other types of risk as well. Thus, a parent with a drug problem is more likely also to have low income and to engage in poor parenting. The phrase *toxic stress* is sometimes used to describe extreme, frequent, or extended stress faced by children without the buffer of protective factors, such as a supportive adult. Such stress can affect the neuroendocrine-immune network and have long-term emotional and even physiological consequences.

Assessing Risk to Children's Development

Nevertheless, it is important to note that most children experience low levels of risk. A number of approaches to assessing risk have been developed, and all tend to demonstrate a similar pattern.

The adverse childhood experiences (ACEs) model is one approach to assessing negative events or circumstances that people may experience. The 2011–2012 National Survey of Children's Health includes a set of measures that assess how many such experiences children have had since birth. Items include parental divorce/separation, a parent's death, inadequate family income, domestic violence, being a victim of or witnessing violence, living with someone with a mental illness, having a parent in jail or prison, and living with someone who had a problem with alcohol or drugs. Analyses of these data indicate that adolescents 12 to 17 years old who have experienced a greater number of adverse experiences are substantially less likely to be thriving. For example, the proportion of adolescents with high levels of behavior problems rises steeply as the number of ACEs increases from 30% for adolescents with no ACEs to 41% for those with one ACE, 50% for those with two ACEs, and 60% for those with three or more ACEs. Fortunately, relatively few adolescents experience a high number of ACEs. Specifically, in the 2011–2012 survey, 32% of the adolescents had not experienced any adverse experiences, while 44% had experienced one, 14% had experienced two, and the remaining 11% had experienced three or more.

Similarly, most children experience low levels of social and demographic risks at the family level. In addition to the ACEs measures, the National Survey of Children's Health assessed five measures of risk to children's development: (1) poverty, (2) living in a single-parent family, (3) parent(s) with low education, (4) family with four or more children, and (5) family unable to own or buy a home. As they do with respect to adverse experiences, most children experience low levels of social and demographic risk. Specifically, 44% had just one risk, 25% had two risks, and 18% had three risks. Only 14% experienced four or all five of the risks. But, again, those children with greater numbers of social and demographic risks also had lower well-being on a number of outcomes.

In sum, risks pose substantial challenges to children's development and well-being, and this pattern is robust across varied definitions of risk. Fortunately, data indicate that only a minority of children and youth face extremely high levels of risk. Given the serious implications of risk for these children, assessments of risk can help identify children who are at high risk and can inform efforts both to reduce risks and to mitigate their consequences for children's development.

AUGUSTINE

St. Augustine (354–430 CE) was Bishop of Hippo, in North Africa, in the last decades of the Roman Empire. A towering figure of Western thought, Augustine's intellectual influence on philosophy and theology has extended for more than 14 centuries in fields far beyond Catholic Christianity. Admired by Protestants as much as by Catholics, his wider impact has been on philosophy, literary history, and theory. Historians of the late Roman Empire remain indebted to the insights his autobiographical *Confessions* provided of daily and especially academic life before the fall of Rome. After outlining salient features of his life, this entry will focus on those elements of his thought that have relevance for religious education, and for moral education more generally.

Augustine's early education was Christian; his mother, Monica, had ensured this. But his youth is marked more by contact with the "pagan" inheritance of classical Greece and Rome. Fond of literary composition and competition, at which he excelled, Augustine also completed a now-lost work on aesthetics. Before his conversion to Christianity, he taught grammar and rhetoric in Carthage and later in Milan.

There is an often-cited account of his conversion in a Milanese garden in 386 CE in which he hears

the instruction to pick up and read a book, which happens to be the Letter of Paul to the Romans, and specifically the passage (Romans 13:13–14) in which St. Paul abjures his Christian readers to avoid reveling and drunkenness, quarrelling, and jealousy, many of which activities Augustine saw in typical self-condemnation as characterizing his youth and early adulthood. This experience led to a period of retreat from the academic duties—he was a professor of rhetoric in Milan—to semimonastic existence at Cassisiacum. This was an important part of his postconversion life.

Under the pastoral guidance of St. Ambrose, Bishop of Milan, Augustine began to see the meaning of human existence as integrally related to the revelation of the scripture and the doctrines of the Church. Later, reluctantly accepting the ecclesiastical post as Bishop of Hippo, Augustine's entire postconversion life can be regarded as an attempt not only to be a guide to his diocese but also to philosophically and theologically defend and justify the orthodox teaching of the Catholic Church, and so his influence extended far beyond the remote corner of North Africa where he was bishop. No understanding of Augustine's impressive corpus of work is possible without seeing not simply a theological motivation but a deeply held and often personally passionate expression of his Christian faith.

Augustine's theological and philosophical output is always an expression of a personal faith, but it is also his perception of his duties as a bishop to guide and defend the faith against error. And, examining his early, preconversion life, there was no person he condemned more and in harsher terms than himself. Augustine is perhaps for this reason arguably most well known for the autobiographical work that charts his long and difficult conversion to Christianity, *Confessions*.

His educational reflections in this important work—as noted, it tells us much about schooling as well as university life in the classical world—are interesting for other reasons. Not least because in his self-recriminatory attack on the first three decades of his life he is adamant in suggesting that, apart from a life of dissipation, one notable impediment to conversion and a life of faith was a life of great learning, or at least learning misdirected.

For Augustine, learning should serve only one ultimate purpose, the seeking of God and through this personal salvation—and this was a position he maintained throughout his life. In a later work, *City of God*—his most significant philosophical and theological achievement—he makes the distinctions between two cities, the earthly city and the city of God. The former and the latter necessarily interact. Those who have found salvation and those who have not are journeying through a life on earth. It is a pilgrimage in which the fate of all individuals will be decided in the Final Judgment. Earthly life is therefore an opportunity to find that salvation through the grace of God. Any way of life that prioritizes the earthly city rather than the City of God, which places the temporal above the eternal, risks an irrevocable loss.

If we see this in Augustine's most noted philosophical and theological works, it is all the more apparent in *On Christian Teaching*, or *On Christian Doctrine*. Here, Augustine deals with matters of teaching and learning in respect of matters of faith. This work took Augustine a surprisingly long time to complete; he started the first of his four books around the time he composed *Confessions*, in 395 CE, but he did not complete the work until some decades later. The central question of *On Christian Teaching* is whether it is right and proper for Christian educators to use the works of classical authors and their techniques of argument (notably rhetoric) for the purposes of Christian teaching. Augustine, a master both of classical learning and Christian doctrine, argues that it is.

This was no arcane matter for Christian educators in Augustine's time. Arguably, it is one on which Christian educators still reflect. Today, it might be the extent to which learning can draw on fields outside of theology and the study of religion (perhaps when these same fields might in their origin and intention have originated in a critique of religion, such as sociology and psychology). For Augustine, it reflects a debate that had been rife from the foundation of the Church and through its early centuries: How far was it legitimate to incorporate classical or pagan philosophy—even those not critical of the faith—into Christian theology?

Augustine develops his argument as follows. Since the highest good and our only ultimate happiness reside in God, it is lawful for a Christian teacher to use the means even of pagan learning, for example, its techniques of rhetoric, if these can be safely directed toward the salvation of souls. From here, Augustine reflects on the different types of learners who might benefit from different types of approaches to teaching. Some learners, he states, are attentive and ready to learn; others require more significant rousing and motivating. It is instructive

to read Augustine closely here, for the matching of approaches to teaching and learning based on individual need is something that most modern educators would regard as critical.

Techniques such as rhetoric may be legitimate, then, so long as they are directed toward salvific ends. Augustine develops his argument further, paralleling a philosophy of education and a philosophy of language. He examines the latter—as modern linguistics and/or philosophers of language might—through an analysis of signs. In this discussion, Augustine highlights two key errors in the interpretation of language: (1) taking the figurative literally and (2) taking the literal figuratively. Augustine does not resolve the problem of truth in language but emphasizes that language in educational or any other context raises issues of truth that are inextricably interrelated to language.

For Augustine, the greatest (educational) problem here is that while the teacher needs eloquence, demonstrated with classical as well as Christian exemplars, in all, it is more important for the teacher to have wisdom: A distinctive feature of strong intellectuals is not the love of words but the love of truth. Augustine talks of a golden key—What use is it, he asks, if it cannot open any door? A wooden key would be far more beneficial if it serves that purpose.

But for Augustine, even more is required of the teacher than skill in the art and craft of teaching. In Chapter 27 of *On Christian Teaching*, Augustine writes that the teacher should mirror the ideals he or she teaches, for "whatever may be the majesty of the style, the life of the speaker will count for more in securing the hearer's compliance"; the teacher "who speaks wisely and eloquently, but lives wickedly, may, it is true, instruct many who are anxious to learn" but will to themselves be unprofitable. "Now these [teachers] do good to many by preaching what they themselves do not perform; but they would do good to very many more if they lived as they preach." "For," writes Augustine, "there are numbers who seek an excuse for their own evil lives in comparing the teaching with the conduct of their instructors." *On Christian Teaching* is thus as much a work of professional ethics as it is of practical theology and pedagogy.

AUTONOMY

Individuals achieve personal autonomy to the degree that how they live must be explained as their own self-government. Personal autonomy is modeled on the self-government of the state, and the most conspicuous failures to achieve it are closely akin to failures of political autonomy. Those who live in fearful or unthinking conformity to the will of others fail to achieve personal autonomy, as do people who habitually succumb to inner drives they cannot control. The former condition is analogous to the state whose independence is subverted by some intimidating neighbor or colonial invader; the latter parallels the state that loses control to rebels within its own borders. An education for personal autonomy entails learning whatever enables human beings to achieve a valued state of individual self-government. This entry explores the long history of autonomy in Western philosophy of education and the controversies surrounding it in contemporary scholarship.

The previous paragraph points to the concepts of autonomy and education for autonomy. Both concepts are open to rival interpretations because individuals can disagree about where in the psyche to locate "the self" that properly rules and for which educational goals and processes are aligned to secure its rightful authority. This might be called the question of privileged location. Thus, we might agree that the concept of autonomy captures the paramount end of education even though our radically different

answers to the question of location entail disagreement about the education necessary to achieve that end.

Autonomy in Ancient Greek Philosophy

Western philosophy of education begins with Socrates in ancient Athens, and so too does philosophical argument about autonomy as an educational end. Because all we know about Socrates comes from the inconsistent writings of those who knew him, the details of what he believed are uncertain. What is clear is that he urged Athenians to subject their beliefs and values to critical scrutiny, to discard whatever was inconsistent or groundless, and to live in light of the truth so far as they reflectively grasped it, even if that led to public condemnation. The unexamined life was not worth living, and each of us must learn to do our own examining.

That is presumably the point of Socrates's notorious claim that he was not a teacher and taught nothing. For if we must learn to think and act for ourselves, we must each become our own teachers at some point. Others may facilitate that process through questioning and by tacitly inviting us to emulate their own autonomy. By such means, the "teacher," assuming for the moment that the word can be aptly used here, serves as a midwife to the birth of another's autonomous self. Thus, in Plato's earlier dialogues, which were likely written under the strong influence of his master, the role of Socrates as midwife/pedagogue is to draw out his interlocutor's own ideas with carefully crafted questions.

How did Socrates answer the question of privileged location? The ruling self resides in our capacity to assess evidence and argument in favor of principles or theories, independently of custom or the alleged expertise and authority of others. By exercising that capacity and encouraging others to do likewise, Socrates believed that we arrive at a humbling sense of how very little we really know and how vast and preposterous are the claims to knowledge that others make. Publicly exposing the ignorance behind others' claims to knowledge is a dangerous task if their prestige or authority is legitimated by these claims. Perhaps it is not surprising that the social subversiveness of Socratic autonomy led to his being charged and executed for corrupting the youth of Athens.

Socrates became a revered figure for later ancient philosophers, and his valorization of reason as the lodestar of human flourishing would become a dominant motif within the tradition. What was distinctive about Socrates among the great Greek philosophers, however, was a conception of reason that exalted the social independence of the examined life and its potential repugnance to the deliverances of all who claimed political or epistemic authority. In the case of Aristotle, for example, it is much less clear that the place of reason in the good life constitutes anything that could be aptly called autonomy. At the core of Aristotelian ethics is the idea of practical wisdom. Those who possess that virtue can reliably identify and choose the mean between opposing vices. We learn to become practically wise by emulating those who are already socially acknowledged as possessing that wisdom, and Aristotle assumes that such people will agree about where to find the mean. The Aristotelian conception of practical wisdom, thus, installs a deep moral conservatism as the fulcrum of his ethical theory and philosophy of education, a conception that leaves no room for the possibility of autonomous dissent and eccentricity of the sort that was celebrated in the life (and death) of Socrates. Virtue becomes conflated with high-minded respectability, and the critical edge of reason is blunted.

Autonomy and the Enlightenment

The advent of Christianity did not create an intellectual milieu congenial to exponents of autonomy. The fallen state of human nature in Christian doctrine is in deep tension with the idea that we can each find the best route to the true and the good by means of self-rule. Only with the dawn of the Enlightenment is there a reemergence of philosophical conceptions of self-rule and concomitant educational programs. Without doubt, the most educationally influential of these was expounded in Jean-Jacques Rousseau's great didactic novel *Émile*.

Among the watchwords of the Enlightenment was "nature," and the novel outlined a process of education from infancy to early adulthood in which conformity to nature was supposed to be the touchstone of good practice. Rousseau can also be interpreted as offering a distinctive answer to the question of privileged location. If *Émile* is to be our teaching manual, the rightful source of self-rule inheres in deep natural propensities that conventional educational practice inevitably thwart.

The novel's first sentence is among the most famous in the history of educational thought: "God

makes all things good; man meddles with them and they become evil." The task of a good education, then, if such a thing is possible at all, is to rear children in a way that keeps faith with the goodness of their nature and eschews the corruption of society. This is hardly a coherent undertaking given that human influence must intrude on the child's environment to elicit any learning above the most primitive level. The novel traces the education of its eponymous hero under the guidance of a wise tutor who systematically orchestrates Émile's experience behind the scenes with particular pedagogical goals in mind. The child believes that he is "learning from nature" when in fact nature has been surreptitiously manipulated to ensure a particular educational outcome. Despite its paradoxes, inconsistencies, and exaggerations, Rousseau's novel was to have a lasting influence on educational thought.

First, the idea that the natural cognitive and emotional development of the child places constraints on the educational process had a seminal influence on subsequent educational theory and practice. To some extent at least, the locus of educational direction has to lie with the child's evolving self and not merely with what is deemed desirable learning by the wider society. If the idea that children must be developmentally ready for what we teach them now seems to be a mere cliché, it is only because of Rousseau's overwhelming influence. Second, Rousseau conceived the developing self not merely in cognitive and volitional terms but also as a broadly affective process. The education of Émile was designed not merely to evoke a stable rational self that would rule against the grain of custom and social prejudice; it would also encompass our natural passions, most notably the compassion by virtue of which self-interest could be muted and reconciled to the interests of others. In its emphasis on the affective richness of human nature, Rousseau's theory paves the way for Romantic ideals of autonomy and authenticity that came to prominence in the late 18th and early 19th centuries.

Philosophical discourse on autonomy and the education suited to its realization has had a complex history since the publication of *Émile*, with important contributions from Immanuel Kant, John Stuart Mill, and others. Kant, for example, wrote a famous essay "What Is Enlightenment?" (1784) that opens with the straightforward statement, "Enlightenment is man's release from his self-incurred tutelage. Tutelage is man's inability to make use of his understanding without direction from another." He attributed this tutelage not to lack of reason but to lack of courage to use it independently.

The 20th Century and Beyond

Since the 1970s, the notion of autonomy has entered a particularly vibrant phase of development that has impinged on some of the most central questions about educational policy in diverse and democratic societies. The major inspiration for this is John Rawls's theory of justice.

Rawls argued that a certain ideal of the person was latent in the public culture of contemporary democratic societies. An essential feature of the ideal was that people must be free to revise their goals in life when new experience and knowledge show them that revision was needed. That is why individual liberty is such a widely cherished part of our public culture, or so Rawls maintained. But if that is why liberty matters, the argument also shows that people need to learn to think critically for themselves if revision to their goals is to be done when desirable. Unlike Socrates, Rawls did not say that the unexamined life is not worth living. But he is clear that the critical capacity to examine our lives—the capacity for autonomy, in other words—is integral to an ideal of the person that democratic citizenship presupposes.

Autonomy is crucial to Rawls's theory at another point. In addition to the capacity to revise our goals in life, Rawls claims that a sense of justice is fundamental to the democratic ideal of the person. Thus, we are all said to have a duty to support just institutions where they exist and to play some part in creating them where they do not. But this assumes that individuals have the interest and intellectual capacity reliably to assess the justice of institutions, which in turn presupposes that they have received an education that cultivates the relevant interest and capacity. An education for autonomy is thus a necessary component to the sense of justice entailed by the democratic ideal of the person.

In his later writings, Rawls emphasized the suitability of his theory of justice for societies in which pluralism was acknowledged as a permanent fact of life. He believed that our failure to come to agreement about many of the most fundamental ethical and religious questions was to be explained by the inherent limits of reason itself rather than by passions or interests that subverted our ability to reason. Therefore, a theory of justice should try to accommodate so far as possible our reasonable disagreements about what is good and right. This

raises an obvious question: Would an education that cultivates personal autonomy in the sense entailed by Rawls's theory really be acceptable to *all* reasonable persons in a democratic society?

Consider the fact that millions of people in currently democratic societies would describe themselves as religious conservatives who believe that obedience to God (or some earthly surrogate chosen by God) is the only basis for living as we should. Teaching children to obey God, according to the strictures of this or that particular religious tradition, and teaching them to cultivate autonomy are tasks that are not always easily reconciled, to say the least. Note that on Rawls's account, the cultivation of autonomy would mean that we should encourage children to think of their conceptions of the good as revisable constructs, to be modified or even abandoned altogether when reason and experience show that we should do so. But if my conception of the good is to follow the biblical Abraham who would even kill his son when he thought it was God's will, the prospect of revising that conception whenever my own reasoning tells me to do so will seem utterly scandalous.

The worry is that Rawls's theory cannot be nearly as accommodating of diversity as he thinks. On the one hand, his sparse explicit remarks about education assure us that any education for citizenship authorized by his liberalism should not be a burdensome or controversial undertaking. On the other hand, the alluring ideal of the person at the core of his theory suggests that an education in keeping with that ideal must substantially limit the scope of religious diversity in extant democratic societies.

But the problem here is not unique to Rawls's conception of autonomy. Any conception of the concept will affirm the value of thinking for oneself and choosing accordingly, and to the extent that it does, conflict with some varieties of cultural and religious conservatism is inevitable. That is as much a problem for adherents of Socrates as it is for devotees of Rawls.

How we should respond to this impasse is not altogether clear. One possibility is that we lack any sufficient reason to favor autonomous overheteronomous lives in the public provision of education. But the argument for democracy has often been thought to depend on the idea that citizens can learn to think critically and independently about justice and the common good and thereby advance these ends through their political participation. Otherwise, no special connection between democracy and these laudable public ends is evident. If education should do nothing to establish the autonomy that enables citizens to discharge their civic duties well, at least one common defense of democracy has collapsed.

The only alternative to autonomy is to surrender our judgments to the will of others. That strategy is dubious not because we should expect people who think for themselves to think wisely all the time. What makes it dubious is the vast evidence we have to distrust elites who have been given the power to dictate how others choose and what they will believe. Sober worries about the fate of those who are intellectually and ethically subordinated in social hierarchies may well give us more than enough reason to cherish autonomy in personal as in political contexts.

To cherish autonomy as a central aim of education does not mean that no other aims are justified or that deference to values outside the realm of education might not properly limit its promotion. More work on these topics would enrich our understanding of autonomy in education. For example, we could reasonably expect that a consequence of cultivating autonomy more vigorously would be the decline of cultural and religious groups that depend on heteronomous loyalty. That would be a loss of diversity. On the other hand, a more widely diffused autonomy could inspire new ways of life, as Mill expected. Could new sources of diversity adequately compensate for the loss of traditional sources? This question and many others about the connection between autonomy and other educational or ethical values will preoccupy philosophers of education for many years to come.

B

Bacon, Francis

Lord Francis Bacon (1561–1626), an English lawyer, statesman, and thinker, is primarily renowned today for his philosophy of science. Writing at the dawn of modernity, he offered a penetrating critique of contemporary sciences, an innovative method for the study of nature, and a revolutionary vision of human progress. While most of Bacon's practical suggestions were never embraced, his vision, which ties together social, technological, and scientific progress, has become one of the building blocks of Western civilization. Bacon's influence on the development of education was profound but indirect. Drawing on Bacon's vision, his adherents played a critical role in shaping education into its present form.

At the basis of Bacon's philosophy stands a rejection of the then dominant view that the sciences were limited to providing a better understanding of the world, and his conviction that their primary aim is to increase humanity's power over nature in order to make life safer, longer, and more convenient. Examining the sciences from this innovative utilitarian perspective, Bacon concluded that they were in a poor state and identified the main causes for it. Bacon points, inter alia in his conception of the "idols of the mind," to what can be divided into two sets of causes. The first stems from the limitations of human nature. According to Bacon, our understanding, modes of association, language, and personal tendencies are inherently flawed and naturally lead us into error and a distorted conception of nature. The second set of causes is the prevailing intellectual traditions of the time. Bacon mounted a devastating critique of contemporary practices, philosophies, and research methods. He argued against the common view that the study of nature and piety conflicted, objected to the fusion of religious and scientific ideas, accused Aristotle of corrupting the natural sciences with his overuse of deductive logic, attacked the excessive individualism that dominated contemporary research, and struggled against superstition and occultism. For Bacon, existing systems of thought not only failed to correct the inherent defects of human nature but also became in themselves barriers to scientific advancement.

Bacon was persuaded, however, that if the reform plan he put forward—mainly in his *The Advancement of Learning* (1605) and *The New Organon* (1620)—were embraced, the limitations of human nature could be overcome and the sciences could rapidly progress.

The key to success, he held, was to render the study of nature systematic. This was to be done through five key mechanisms. First, religion and the natural sciences were to be separated and all existing intellectual traditions abandoned. Second, all forms of human learning were to be mapped and classified into different branches. Third, rigorous and comprehensive data collection was to take place in each branch of the natural sciences. Here, he also advocated a reform in the methods of data collection. Bacon held that observations must be made the principal tool for studying nature, but his greatest innovation in this domain lay in his belief that man-made manipulation of nature, namely, experiments,

is an important means for acquiring knowledge. Fourth, eliminative induction was to be used in order to derive general principles from the data collected. In this complex process, phenomena that share a common feature, for example, that they produce heat, had to be broken down into their most basic elements and the general cause responsible for their common feature, producing heat in our example, identified through the elimination of all alternative possibilities by way of comparison. Finally, research was to be kept public and preferably institutional to enhance the method's effectiveness. If this program were followed, Bacon argued, humanity could gain power over nature and ameliorate life.

Bacon even provided a vision of what life could look like if the sciences advanced. In his unfinished utopian novel *New Atlantis* (1627), which was published posthumously, he portrays a technologically advanced society in which all people enjoy a comfortable life after nature has been conquered, scarcity eliminated, and life prolonged through the work of a central research institution.

Historically, Bacon's proposed method of scientific investigation was far removed from the one that actually led to the development of science and technology. Although Bacon has been credited with some important innovations, such as stressing the role of observation and experimentation, his method has been severely criticized for ignoring the importance of mathematics, for seeking localized technological advancement instead of comprehensive scientific theories, for overemphasizing induction, for disregarding the role of hypothesis in scientific development, and for aiming at an impossible goal—the complete domination of nature. These weaknesses in Bacon's theory have even led some to cast doubt on his contribution to philosophy. On the other hand, Bacon's vision of a scientifically and technologically advanced society has proven to be extremely influential. Within a few decades, Bacon's program of institutional scientific research aiming at useful discoveries led to the establishment of national societies for the advancement of science in England, France, and, later, the rest of the world. In the 18th century, Bacon's vision of progress was adopted by the thinkers of the Enlightenment and woven into the substructure of modern Western thought. Ever since, the innovative link created by Bacon between scientific progress, technology, institutional research, and improvement of living conditions has steered, despite the growing critique of it, the development of Western culture.

Bacon's vision has also had a momentous impact on the formation of modern education. Although he hardly wrote on the subject per se, Bacon's views have important educational implications, which were developed by his followers. Inspired by Bacon, 17th-century reformers such as Johann Amos Comenius argued that education was essential for preparing the ground for scientific progress. Accepting the aims of Bacon's program, Comenius held that it implied reform not only in research but also in education. To secure scientific progress, Comenius maintained, education has to be made systematic and universal. In the 18th century, plans for a national educational system were drafted with Bacon's ideal of progress in mind. In these plans, education and the curriculum were reoriented toward the practical and increasingly seen as serving science and technology. Eventually, in the 19th century, educational systems were erected along the same lines. At present, Western educational systems are still guided, perhaps even increasingly so, by Bacon's vision of progress. It is Bacon, therefore, who, for better or worse, set the framework in which our educational systems currently function.

Beauvoir, Simone de

The French writer, philosopher, and activist Simone de Beauvoir (1908–1986) is recognized as one of the most significant intellectuals of the 20th century. Her primary writings date from the 1940s and 1950s, although she wrote her first philosophical

piece while still a secondary school student. Her often literary style contributed to a changed conception of philosophy in Continental intellectual life. Her writings included novels and plays, letters and diaries, and several volumes of autobiography, along with more traditional philosophical essays. Although still contested, it is important today that her philosophical occupation across these genres be emphasized. Beauvoir is best known for contributions to two philosophical arenas: existentialism, with its connections to phenomenology, and Marxism, and to a birthing of modern feminist theory. In these areas, her work has been of interest to contemporary philosophers of education, especially but not exclusively those concerned with feminist issues and Continental thought. Her writings continue to serve as an important and empowering model for new generations.

Central to Beauvoir's philosophy is her biography. She was born in 1908 into an upper-middle-class Parisian family that underwent hard times; her mother especially sacrificed a lot for her two daughters. They had a traditional Catholic girls' education, and Simone, without a dowry, prepared to go to work. She studied mathematics and science (opened only a few years earlier to female students) and graduated from two preparatory schools in these subjects as well as in literature, Greek and Latin, and philosophy. Although not allowed to enroll, she gained access to courses at the Sorbonne and lectures at the École Normale Supérieure, the premier national institution for all teachers of philosophy. In 1929, she became the youngest woman ever to earn the national degree in philosophy. Her economic security was realized initially in employment at *lycées*, the well-known regional secondary schools in which most philosophers taught.

During the period when she was studying for the degree, she met Maurice Merleau-Ponty and Jean-Paul Sartre. In the national exam, the legend is that the judges debated hotly whether to award first place to Beauvoir or Sartre; perhaps he was given the highest rank because he was male. Merleau-Ponty remained a true friend throughout her life, and Sartre, as is well known, was her "significant other" personally and professionally. Together the three spearheaded the existentialist movement (a movement that rose, briefly, to a prominent position in the philosophy of education in the United States in the late 1950s to early 1960s).

Beginning in 1943, the first of five novels appeared; the fourth, *The Mandarins*, earned her the nationally prestigious Prix Goncourt in 1954. Her first philosophical essay was published in 1944, and the two most important philosophical texts followed: *The Ethics of Ambiguity* in 1947 and *The Second Sex* in 1949.

Today, it is well understood that Beauvoir was always a philosopher, even as she resisted the label. This was perhaps due to her perception of "prejudice" against women intellectuals of her generation and to her own "debt" as the protégée of Sartre. Her personality strongly figured in her philosophical approach; she was an often unconventional, intense, passionate, and highly introspective person. Overall, she envisioned philosophy in nontraditional ways. First and foremost, while standard philosophy was abstract and oriented toward universal system building, this was not her orientation. Instead her approach was concrete and situational, a view named "the philosophy of lived experience." It focused often on the everyday lives of persons, of self and others, and was more ethical and political than epistemological. This foundational experience was universal, common to everyone, but it was also particular, as it differed for each. For Beauvoir, experience for women was importantly distinct from that of men.

Recent commentary on Beauvoir's philosophy has recognized its affinity to contemporary poststructuralist writings. She was not part of this tradition, but central concepts in her work do resonate with later French philosophers. These ideas include ambiguity, embodiment, subjectivity and intersubjectivity, and freedom. For her, an ethics resulted. To begin with, ambiguity is basic to the human condition, shared by all, and it is something to be embraced. In her text *The Ethics of Ambiguity*, there is no philosophical "search for certainty" and no detached thinker. Ambiguity arises out of experiencing the inevitable tensions of the world.

Ambiguity is tied not only to consciousness but also to a materiality: Humans are embodied. In *The Second Sex*, Beauvoir introduces the distinction between sex and gender and, in analyzing the way in which women experience their bodies, shows that embodiment is central to experience, to making choices, and to carrying out actions. Bodies are key in subjectivity.

Beauvoir's third concept, subjectivity, is used in dealing with the modern problem of the relationship of self to the world, especially to others: Each self has a desire to be, to achieve a transcendence that cannot be realized. The self is always at once both solitary and potentially in solidarity, interrelated to others. Unlike some other existentialists, in

Beauvoir's philosophy, subjectivity and intersubjectivity are one and the same and are constitutive of existentialist freedom.

Finally, Beauvoir's philosophy aims for a "new synthesis," an ethics that retains a modern rather than a postmodern aim. Out of this ethics, a politics emerges that incorporates the ambiguity and indeed the practical failures of everyday life—multiple paths for action may be seen to be possible, but the choices that are made are ultimately pragmatic, for God, state, or Other cannot be relied on for life's answers. There is only the lived experience of all.

Especially her contributions to existentialist and feminist theory, and to the politics that resulted, remain significant for contemporary philosophy of education and for all educators committed to social justice.

Behavioral Objectives and Operational Definitions

The topic of behavioral objectives in education is clearly distinct from that of operational definitions. They have a different origin, since the behavioral objectives movement arises out of behaviorist theory in psychology, while defining concepts "operationally" originated in the quest for clarity in meaning in scientific and everyday life. Though logically distinct, behaviorism and the behavioral objectives movement latched onto operationalism as a method for combating introspection as a source of knowledge of psychological processes and as a way to rid psychological concepts of subjective meaning in the quest for an objectively verifiable science of behavior. This entry discusses operationalism, behavioral objectives, and their use in education, and criticism of the behavioral objectives movement.

Operationalism

"Operationalism" was given full-blooded treatment by the Nobel Prize–winning physicist P. W. Bridgman in *The Logic of Modern Physics* (1927), though his operationalism was anticipated by the work of the American pragmatist philosopher Charles S. Peirce. Peirce (1878/1992) formulated a particular pragmatic maxim of operational intent as follows: "Consider what effects, which might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object" (p. 132). Peirce insisted that this maxim is about meaning—a "maxim of logic"—simply a method for more clearly defining one's terms. Like Peirce, Bridgman was concerned with how to make our concepts clear and distinct. Bridgman was greatly concerned that physicists had imported terms from one area of physics into another without recognizing that the same term no longer picked out the same concept. The result was conceptual confusion and theoretical dissolution. So Bridgman (1927) turned Peirce's pragmatic maxim into a more explicit operational maxim: "In general, we mean by any concept nothing more than a set of operations; the concept is synonymous with the corresponding set of operations" (p. 5). Bridgman here used the example of length in illustrating his operational maxim: Its meaning is given by the various observable and repeatable procedures and operations. Such a stance, if taken literally, however, creates problems of its own. It seems to imply that different procedures and operations create multiple concepts of length, all with different meanings, when what is wanted is one concept of length, if possible, with multiple ways of determining it. Despite the misfortunes of operationalism as a method for determining the meaning of

scientific concepts, it is the tough-minded spirit of operationalism that moved behaviorist psychology to adopt its attitude and prefer operational definitions cast in behavioral (observable) terms in dealing with educational objectives.

Behavioral Objectives

In the modern era, J. F. Bobbitt's *The Curriculum* (1918) stands out as the first influential text advocating the design and selection of educational objectives; as an "efficiency expert," Bobbitt extolled the use of objectives in curriculum planning. Though differing with Bobbitt's utilitarian approach and rooted within the progressives' emphasis on individual development, Ralph Tyler (1949) extended Bobbitt's embrace of educational objectives with an additional focus on their evaluation in his influential *Basic Principles of Curriculum and Instruction*. This book arose out of Tyler's experience as the lead evaluator of the "Eight-Year Study" (1933–1941), a Progressive Era attempt to recast high school curricula.

As Tyler narrowed his focus to evaluation of the attainment of educational objectives in curriculum planning, he advocated the formulation of objectives in more specific terms to permit finer-grained assessments of student learning. Though still fairly general in scope, these objectives could then be related to content and student behavior in the business of planning. Tyler and his students—for example, Benjamin Bloom, chair of a committee that produced the influential *Taxonomy of Educational Objectives* (1956) and its follow-ups—could scarcely be considered to be "behaviorists," given their holism and their integration of the cognitive and affective domains of human experience, along with the psychomotor, into their work. However, their growing tendency to emphasize the connection between behavior and evaluation, through testing, prepared the stage for the "scientific asceticism" of behavioral objectives.

Behaviorism operationally defines learning not in cognitive or mentalistic terms but as a more or less permanent change in behavior. In particular, the influential psychologist B. F. Skinner often defined learning operationally as nothing other than changes in the frequency of a behavioral response (see, e.g., Skinner, 1953). The behavioral objectives movement has taken these operational definitions of the concept of learning seriously in determining the full range of educational objectives, asserting that all meaningful educational objectives should conform to a behavioristic specification. This sets a problem noted by R. H. Ennis (1964): "How can we give operational definitions without unduly restricting the meaning of the terms in which we state our conclusions?" (p. 183). In other words, does the behavioristic definition of learning unduly restrict the language of educational objectives across the cognitive, affective, and psychomotor domains noted by Bloom and colleagues? It might be thought that the greatest difficulties for a behavioral treatment of educational objectives arise in the cognitive and affective domains. But even psychomotor learning in education may elude a behavioristic analysis.

Strongly influenced by Skinner and others, R. F. Mager returned the analysis of educational objectives back to the preprogressive, utilitarian strain introduced by Bobbitt. He drew his inspiration from factory and military settings that featured stepwise functions in the completion of a product or task. His *Preparing Objectives for Programmed Instruction* (1962) became a sensation in certain quarters and codified the approach to behavioral objectives in education. In dealing with the cognitive domain, Mager expunged terms such as *knows*, *believes*, *understands*, *feels*, *appreciates*, *grasps the significance of, acknowledges*, and so on, in the construction of objectives because they implicated unobservable, subjective, mental events and states that could not be controlled for, replicated, or measured. He permitted only terms that seemingly implicated "overt" behavior that could be replicated and measured: *puts*, *points*, *circles*, *recites orally*, *removes*, *sorts*, *counts*, *underlines*, and so on. Other, "softer" proponents of behavioral objectives realized that not all mentalistic-infected terms could be dispensed with in the construction of objectives without impoverishing educational discourse or narrowing the phenomena of teaching and learning. However, they require that a behavioral indicator accompany each use of a cognitive term. As for the affective domain, if not exorcized (since there is no use for mentalistic or internal terms such as *feels*, *fears*, *motivates*, *intrinsically satisfies*, etc.), at best such terms are subject to dispositional analysis in terms of behavior.

According to Alberto and Troutman (1999), the construction of each behavioral objective should identify four elements:

1. The person(s) for whom the objective is written (the learner)
2. The behavior targeted for change
3. The conditions under which a behavior will be performed

4. Observable criteria for determining when the acceptable performance of the behavior occurs

The desired behavior itself should be clearly specified in operational behavioristic terms, something that is repeatedly observable, and its extent measurable, and the conditions of learning clearly specifiable and repeatable.

In later years, Robert Mills Gagné and Leslie J. Briggs (1974) incorporated the notion of a learned-capability aspect into the specification of objectives that indicates the kind of learning category for the intended behavior. Otherwise, a silo might envelop each behavioral objective. This treatment by Mager, Gagné, and others has been quite influential in education, even if there has been little understanding of the psychology and philosophy from whence it rose. In education today, the behavioral objectives movement is especially strong in test design and measurement, assessment, special education, and instructional design. We may see the latter at work in many colleges' departments of educational technology.

Critique

The behavioral objectives movement suffers from the same defects that plague psychological behaviorism; the attempt to account for all learning as merely changes in behavior is similar to the way Skinner's behavioral reinforcement induced his pigeons to dance—they made a series of movements, mechanically, to receive food but had no conception that they were "dancing." But propositional learning that results in understanding or grasping the meaning of something, on the face of it, simply cannot be banished or reduced to simple behavioral learning—learning to appreciate a poem, for example, has no strict behavioral "indicator." Coming to be a person who maintains certain moral principles and beliefs as a result of study, reflection, and education is a kind of "learning to be" that appears to elude any facile deconstruction into stepwise behavioral elements. Gestalt psychology's analysis of insightful learning, "ah ha!" moments of connecting separate events or ideas, and cognitive psychology's necessary recourse to "mentalistic" concepts makes far more sense of the phenomena elucidated by Bloom and colleagues' taxonomies than Mager's curt dismissal of most of them.

Finally, there is behavioral learning. Here, behavioral objectives might find a home in education. The question, however, turns on another: Did Skinner really induce his pigeons to *dance?* As pointed out earlier, using operant conditioning, he trained them to repeat dancelike movements, and doubtless, their behavior looked like a dance, given their precise steps in a pretty pattern. And doubtless we could easily write a perfect behavioral objective for the pigeons and confirm it repeatedly. But did they really learn to dance? T. F. Green's (1964) analysis of learning the complex activities that we teach in education, including dance, yields a resounding "no." Learning such rule-governed activities, he urges, requires acquiring a norm that invites not simply conformity but obedience to it, and a capacity for making critical judgments of one's own performance and that of others. Moreover, to reduce teaching to bringing about behavior conformity is to misconceive it—teaching ultimately should be aimed at the enlargement of the human capacity for action and the critical capacity for judgment, what Israel Scheffler (1965) has called "passing on those traditions of principled thought and action which define the rational life for teacher as well as student" (p. 143).

In this way, the combination of behavioral objectives with an unsatisfactory, reductionist operational definition of "learning" can be an immense source of mischief, if not danger, in education.

Behaviorism

Behaviorism, or "the science of behavior" as some of its adherents occasionally called it, is a broad movement in psychology that evolved during the early decades of the 20th century—although its roots can be traced back, through British empiricist philosophers such as John Locke and David Hume in the late 17th and early 18th centuries, to the ancient world (several behaviorist principles can be found in Aristotle's *De Anima*). Focusing originally on animal and human learning, the modern movement broadened during the 20th century, and behaviorist approaches can be identified in many of the social sciences and even more widely afield—for example, the Oxford philosopher Gilbert Ryle's *The Concept of Mind* (1949) is often identified as a major work in the philosophical behaviorist tradition. This entry first identifies the basic concepts underlying behaviorism and then describes the approaches taken by John B. Watson, Edward Thorndike, B. F. Skinner, and Ryle.

The Basic Orientation

In defining psychology as the science of behavior, the behaviorists were staking out a position that was in revolutionary contrast to the traditional account, in which psychology was the study of mental life. The three factors that directly shaped this revolution were stated clearly enough in the feisty opening lines of an essay in the *Psychological Review* (1913) by John B. Watson (1878–1958)—who, two years later, on a rising tide of popularity, swept into the presidency of the American Psychological Association:

> Psychology as the behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is the prediction and control of behavior. Introspection forms no essential part of its methods, nor is the scientific value of its data dependent upon the readiness with which they lend themselves to interpretation in terms of consciousness. The behaviorist, in his efforts to get a unitary scheme of animal response, recognizes no dividing line between man and brute. (1913/1948, p. 457)

Awareness of these factors did not begin with Watson; they were part of the intellectual environment of the human sciences. First, if psychology was to be categorized among the sciences, it had to be possible to carry out experiments and test its hypotheses, which would entail making measurements and observations that would result in data that were publicly accessible and thus open to replication or rejection within the scientific community. None of this seemed possible if the focus was on mental or conscious events (which were private to the individuals having them); the same difficulty did not exist with behavior. Second, the method by which conscious life was investigated—introspection, or observation of one's own "inner" mental processes—faced several difficulties. Practitioners of introspection produced accounts of "inner" or mental experience that sometimes were in conflict, and there was no apparent way to resolve these differences, no way to put the rival accounts to the test. Added to this was the obvious difficulty that it was problematic to suppose that a person could accurately observe his or her own conscious processes while at the same time being fully engaged with them—for example, trying to remember some complex event or entity while at the same time making detailed observations about what this remembering process entailed. (Ryle and other philosophers have pointed out that the use of "inner" in accounts of introspection is a metaphor, a point to which the discussion will return.)

The third factor alluded to by Watson was one traceable to the impact of Darwin's *On the Origin of Species* (1859). Although in this work Darwin studiously avoided mentioning the evolutionary origins of the human race, it was clear—and was made explicit in his later writings—that he regarded *Homo sapiens* as part of the animal kingdom and as related to other animal species by way of evolutionary "descent." Thus, Darwin established "genetic continuity" within biological nature, according to which

principle there was "no dividing line between man and brute." One consequence of this for psychology was that the techniques used to study animal behavior by the so-called comparative psychologists could also be used to study humans, for humans also were animals; and just as the study of animal psychology was progressing without (necessarily without) the use of introspection, the same might be expected with respect to the psychological study of humans.

The Behaviorism of John B. Watson

Watson's behaviorism built on the work of the Russian physiologist Ivan Pavlov on conditioned reflexes. Pavlov had found that in naturally occurring reflexes, in which a stimulus automatically produced a specific response (the sight of food producing a flow of saliva in a hungry dog was the classic case), if a second stimulus was regularly associated with the natural stimulus (if, e.g., a bell was sounded when the food was presented), then this second stimulus eventually would be able to elicit the response by itself—it would have become a "conditioned stimulus." Watson used this mechanism to explain how humans acquired their individual repertoires of behavioral traits. In one notorious experiment, he showed how a young child (Albert) could acquire a fear of white furry animals (perhaps even of Santa Claus with his white flowing beard!). Albert was allowed to play with a tame white rat, and then the experimenter frightened him by striking, behind his back, a loud gong. The natural reflex here—a stimulus of a loud noise producing the response of fear—became transformed into a conditioned reflex in which the sight of a white furry animal became a conditioned stimulus that produced the fear response. In his book *Psychological Care of Infant and Child* (1928), he argued that careless parents were responsible for conditioning all of their children's bad habits and fears in a similar fashion, and he referred to the psychological "sledge-hammers" that existed in the home. But, fortunately, the very same processes of conditioning, properly directed, could lead to salvation. In his book *Behaviorism* (1925), he made this bold determinist claim: "Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select" (p. 104).

Some reviewers were swept off their feet by the possibilities raised by Watson, but others—perhaps more discerning?—were appalled. Aldous Huxley produced a book-length response to Watson, his novel *Brave New World* (1932), which depicted a future in which babies were mass produced from bottled embryos and then subjected to schedules of conditioning to equip them with the attitudes and abilities the leaders of society deemed fit. In a scene that could only have been based on Watson's experiment with young Albert, Huxley (1932/1958) described how youngsters in the "brave new world" were conditioned to have a lifelong fear of books: As the babies crawled toward brightly colored, attractive books that had been laid out, suddenly "there was a violent explosion. Shriller and ever shriller, a siren shrieked. Alarm bells maddeningly sounded." The passage ended with the chilling words "What man has joined, nature is powerless to put asunder" (pp. 28–29). Watson seemed undaunted by such criticisms; but in an interesting twist of fate, he left the academic world due to personal difficulties and took his behavior-shaping skills to the world of advertising, where he had a successful second career.

Apart from the moral issues raised against Watson, and the practical problems of putting his deterministic vision into operation, there was an important theoretical problem—the mechanism of classical conditioning that he took as basic for shaping behavior depends for its effectiveness on locating natural reflex mechanisms that had the desired responses as their built-in end point (fear, interest, or whatever) and in which the natural stimulus leading to these end points could be replaced by conditioned stimuli. As the number of suitable natural reflexes is extremely limited, the mechanism of classical conditioning is necessarily of limited educational use. However, there is another mechanism available that offers greater possibilities for the behaviorist's educational dream of shaping behavior. This mechanism was investigated around the turn of the 20th century by E. L. Thorndike and studied further, refined, and applied in a variety of ingenious ways around the mid-20th century by B. F. Skinner.

E. L. Thorndike and the Law of Effect

Thorndike (1874–1949) started his research into animal learning while a doctoral student at Harvard—he kept his experimental subjects, chickens, in the basement of the home of his advisor, William James. He moved and completed his studies at Columbia University and soon joined the faculty of Teachers College, Columbia, where he remained for about

40 years. In contrast to Watson, who focused on substituting or conditioning a new stimulus to replace the naturally occurring one in an in-built reflex arc or S–R (stimulus–response) connection, Thorndike was interested in the effect of repetition and also in the effect of rewarding of the responses that animals made to the situations they were in. He found that the more often a particular response was made in a given situation, the more the connection or association between that situation and that specific response was "stamped in"; later, his position came to be known as connectionism, but its relation to the associationism that stemmed from the British empiricist philosophers was also evident (although their focus had been on association of ideas, not on association between situations and the behavioral responses to them). Thorndike also found that if a response led to a favorable outcome (i.e., if it was rewarded or reinforced), this behavior was more likely to occur again in a similar situation. This can be illustrated by one of his famous studies on cats: If a hungry cat is imprisoned in a suitably constructed cage, outside which is located a "reward," such as a bowl of milk, the cat eventually will, by way of its random thrashings about, hit an escape mechanism and thus gain access to the reward. On subsequent imprisonments, the cat will repeat this behavior, but the time taken for the animal to escape will decrease as it learns—via reinforcement—to hit the mechanism. This finding could be depicted in the form of a so-called learning curve, and it also was formulated in general terms as Thorndike's famous "law of effect," which stated that an act in a particular situation will be more likely to recur if it "produces satisfaction," and it will be less likely to recur if it produces "discomfort." The rewarding of desired behaviors on the part of a student and the punishing of undesired behaviors, of course, are important strategies virtually taken for granted by teachers.

Several lines of criticism of Thorndike's work emerged. First, although his scientific work was of high quality, Thorndike was so convinced that careful laboratory studies such as those described above pointed the way to improvement of teaching practices in schools that he found it unnecessary to actually carry out studies or make observations in real classrooms. It is a common experience among researchers, however, to find that laboratory findings do not hold up in uncontrolled real-life situations. (It is worth noting, in passing, that Thorndike also carried out important laboratory studies on the issue of transfer of learning, discussed elsewhere in this encyclopedia.) The point was also made that Thorndike's experimental designs constrained what he could discover—in essence, by placing animals in situations where intelligence was of no use to them (e.g., by placing them in a cage with a "secret" escape mechanism that could be triggered by chance), he "found" that intelligence played no role in learning and that the process could be fully explicated in terms of repetition and reinforcement. In contrast, the German Gestalt psychologist Wolfgang Köhler, who made this criticism, placed his experimental subjects—chimpanzees—in situations involving problems for which the elements of an intelligent solution were available to them (and he discovered that they did, indeed, reflect and act intelligently!). The philosopher Bertrand Russell (1927/1960) brilliantly summarized this whole situation:

> One may say broadly that all the animals that have been carefully observed have behaved so as to confirm the philosophy in which the observer believed before his observations began. Nay, more, they have all displayed the national characteristics of the observer. Animals studied by Americans rush about frantically, with an increasing display of hustle and pep, and at last achieve the desired result by chance. Animals observed by Germans sit still and think. (pp. 32–33)

B. F. Skinner and Operant Conditioning

Thorndike's work on learning was built on by a number of subsequent researchers, of whom the best known was the Harvard psychologist B. F. Skinner (1904–1990). In addition to his experimental work, Skinner popularized his ideas by way of a utopian novel, *Walden Two*, depicting a society that was organized on behaviorist principles and also through inventions, books, and essays—some of which contained lively philosophical argumentation and all of which were marked by clear and often provocative prose. Using rats, he studied "schedules of reinforcement" and found that to be "stamped in," a target response need not be reinforced every time it occurred—indeed, responses that had been intermittently and randomly reinforced persisted longer after reinforcement ceased than did responses that had been rewarded every time they had occurred. He demonstrated that a pigeon could be taught to dance in a rather short period of time by sequentially reinforcing random movements it made that happened to be in directions required by the dance. He

developed the "teaching machine," which delivered programmed instruction; the material to be learned was broken down into small units, each followed by a few questions, and if these were answered correctly, the learner was immediately reinforced by positive feedback and then allowed to proceed to the next small unit. Skinner called this process of reinforcing desired behavior that had been randomly generated in response to a particular setting or environment "operant conditioning" (for the target behavior was, of course, operating on that environment or situation).

Skinner was outspoken in his insistence that psychology must focus on observable behavior. He had studied some philosophy of science when logical positivism was influential, and thus he held that offering explanations of human behavior in terms of unobservable inner entities (ideas, motives, etc.) certainly was unscientific and possibly meaningless. He attacked the notion that humans were capable of acting autonomously by arguing that this transferred the causes of human action from environmental factors (e.g., rewards and punishments) to an unobservable and mysterious "inner" entity—to an inner autonomous, ghostlike creature. Nevertheless, he offered a small but carefully worded concession:

> A purely private event would have no place in a study of behavior, or perhaps in any science; but events which are, for the moment at least, accessible only to the individual himself often occur as links in chains of otherwise public events and they must then be considered. (1953/1966, p. 229)

This opened the way for psychologists to take seriously the existence of so-called intervening variables, and it possibly was a response to the work of another behaviorist, E. C. Tolman (1886–1959), who had produced evidence that seemed to indicate that rats running through a maze produced a mental map that could guide them when certain aspects of the layout of the maze were changed. (With hindsight, Tolman's work can be considered the point at which behaviorism started to erode.)

Skinner's work is subject to several criticisms. First, the relationship between behaviorism and the logical positivists' rejection of metaphysics (displayed in both Skinner's and Watson's attitudes toward unobservable inner processes or entities), which at the time appeared to be a strength, is now likely to be regarded as a weakness—for attitudes toward metaphysics have softened, and while metaphysical statements are untestable, nevertheless they can be discussed meaningfully and held open to criticism. Second, Skinner's attempt to account for all learning in terms of operant conditioning does not seem viable; there are many different types of learning, some, although not all, of which are given short shrift when discussed in purely behavioral terms. For example, learning a complex thing like Einstein's general theory of relativity does not seem explicable in terms of a mechanism that centers on reinforcement of randomly generated correct responses—how could one randomly generate a correct response to an involved question about relativity unless one actually understood the theory? And, of course, understanding is an "inner" mental process. The so-called cognitive revolution in psychology was able to make headway on matters such as this, and interest in behaviorism gradually faded. Another serious blow to Skinner came in a review of his behaviorist theory of language acquisition, written by the linguist and philosopher Noam Chomsky in 1959. Chomsky showed, among other things, that there were linguistic phenomena (such as the ability of youngsters to understand statements that were formulated using grammatical constructions that they had never come across before) that could not be accounted for in terms of reinforcement of responses.

Gilbert Ryle's Behaviorism

Not all philosophers agree that it is accurate to regard Gilbert Ryle as a philosophical behaviorist, but undoubtedly many of the issues he discusses in his *The Concept of Mind* (1949) are strikingly similar to those tackled in a more philosophically simplistic way by Watson and Skinner. The opening chapter of his book contains a lucid description of what he variously called the "Official Doctrine," "Descartes' Myth," or "the dogma of the Ghost in the Machine" and which he argued is "absurd." According to this dogma, a person is made up of two different entities—a physical body and a nonphysical mind that exists in time but not in space (which is why it cannot be directly observed). Thus, the events that occur in this latter entity are "inner" and private and can only be accessed by introspection. Ryle (1949) holds that "this antithesis of outer and inner is of course meant to be construed as a metaphor, since minds, not being in space, could not be described as being spatially inside anything else" (p. 12). From this dualism of mind and body, there also arises the intractable problem of how the immaterial mind can interact with, and affect the

actions of, the material body. He goes on to argue, among other things, that the dogma of the Ghost in the Machine generates a vicious regress: Intelligent behavior is made what it is, according to this absurd account, because it is caused by prior decisions and commands issued by this "inner" Ghost; but the Ghost's decisions can themselves sometimes be intelligent and sometimes unintelligent—so the Ghost must itself harbor some "inner" entity that makes its decisions intelligent or not, and so on! According to Ryle's account, a behavior is not made intelligent or skilled by what occurred prior to it in some mental domain; the behavior is *itself* intelligent or skilled.

Despite the criticisms that have accumulated over the years, the influence of behaviorism lives on in behavior modification regimes used in institutions, such as prisons and some psychiatric institutions, and, of course, it is present whenever a teacher or a parent praises or otherwise rewards a child for an achievement.

Bell Curve

The bell curve, also called the normal curve, is a graph shaped like a bell representing the symmetrical distribution of quantities around a midpoint when the median approximates the mean. The bell curve was originally designed to display binomial probability (coin toss) of infinite trials: the more times you flip a coin, the higher the probability that you will accumulate an equal number of heads and tails. However, the meaning of the bell curve has been radically transformed since its invention in the 1700s. Assumptions about bell-curve distributions have influenced epistemology, research protocols, and assumptions of normality in education. The bell curve has recently taken on more colloquial meanings (e.g., "grading on a curve"), and new debates have arisen since the publication of Richard Herrnstein and Charles Murray's (1994) *The Bell Curve*, which argued in terms of race that genetically heritable IQ (intelligence quotient) is the basis of socioeconomic inequality.

Throughout its history, the bell curve has functioned variously as a model of coin tossing, a means of reducing error in measurement, a model of a godly universe, fabrication of the Average Man, a depiction of patterns in population aggregates, a standard of normality in which average means ideal, and the assumed basis for racial discrimination. This entry examines both the history and current implications of the bell curve for educational theory and philosophy (Figure 1).

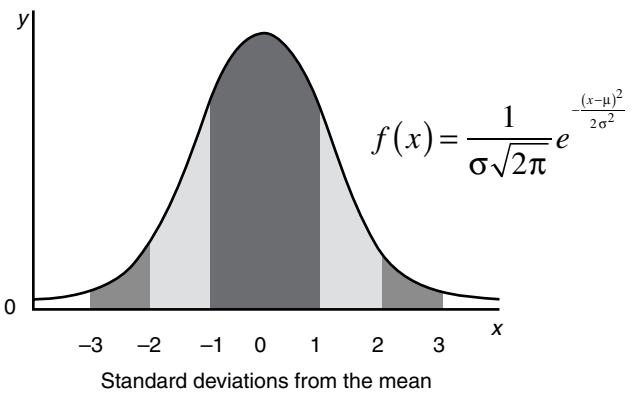

Figure 1 The Bell Curve Graph and Equation

History of the Bell Curve

The bell curve was invented to display binomial probability density and also as a mechanism for reducing error in astronomical measurements. From Abraham De Moivre's calculations in the early 1700s, the bell curve began as the "doctrine of chances." Early work on the bell curve contributed to Poisson's law of large numbers and influenced Maxwell's theory of kinetic gases. During the 1800s, the bell curve underwent several transformations before culminating in modern understanding as the assumed basis for normal distributions of empirical things in the social sciences.

Moral Statistics

Modern social sciences tend to treat the bell curve as if it were the product of empirical inference, a generalization derived from repeated measurements that consistently revealed bell-curve patterns of distribution. However, the history of the bell curve suggests otherwise. The bell curve was not discovered through empirical inference; it was posited a priori in the 1840s by Adolphe Quetelet, a Belgian statistician and astronomer. Quetelet believed that mathematical regularity was a sign of moral perfection. Extrapolating that a universe created by God would not be chaotic or asymmetrical, Quetelet supposed that empirical phenomena (including tides, births, and crimes) *must* be distributed in a bell curve, and it was the task of social scientists to create the statistical mechanisms that would make divine regularity apparent. He assumed that social phenomena would show the same regularity as celestial bodies. Quetelet began with a theological belief in the moral superiority of bell-curve distributions and superimposed the bell curve as the a priori model for data distribution in the empirical world.

Quetelet's reconceptualizations made it possible to export the bell curve from mathematics into social science. Social sciences then constructed quantification and statistical mechanisms that would tidy up numerical occurrences until they fit a bell-curve display. The modern 19th-century quest to establish grand narratives (explanations that were claimed to apply universally) provided a hospitable environment in which bell-curve thinking could flourish.

In sum, the bell curve does not exist in nature; it was imported from mathematics and superimposed on the social sciences as a theologically inspired organizational mechanism to make distributions in the empirical world appear as if they were mathematically regular.

Ideal Type

In the 1750s, the mathematician Thomas Simpson had used the bell curve as a means to reduce error in astronomical calculations: Multiple measurements of distances were averaged to approximate accuracy; outlying measurements were judged to be more erroneous the further they lay from the mean. In the 1840s, Quetelet imported this model of error reduction from astronomy into the social world. Remarkably, he reasoned that if taking the average of distance measurements would help us determine what was accurate in astronomy, then taking the average of human measurements could help us determine what was normal for a human being. Quetelet's statistical innovations created the concept of the Average Man (*l'homme moyen*), based on the assumption that the arithmetical mean of human characteristics is ideal or normal, and outlying features are indications of error or deviance. Quetelet also promoted the idea of "social physics," the belief that people en masse would behave according to the laws of physics. These innovations helped transform the bell curve from a representation of descriptive averages to a prescriptive ideal that has shaped modern beliefs about normality and abnormality.

Theoretical Implications of the Bell Curve

The bell curve forms the basis for much research design and social classification in education. In theory and philosophy, it is relevant to epistemology, normalization, and test design. The assumption of bell-curve distributions for investigating human qualities reflects and sustains beliefs in social inequality in which most people are perceived to be normal or average, while minorities are classified as exceptional or deviant.

Epistemology

Statistically speaking, there are two issues with bell-curve applications. First, the proper display of binomial probability distribution is a bar graph (which represents binomial variables), not a bell curve (which represents continuous variables). Second, the bell curve was originally constructed as a model for the distribution of *random* variables, not as a model of distribution for variables that are *not* random. Nineteenth-century critics rejected Quetelet's appropriation of the bell curve as a model

of the empirical world. Auguste Comte (founder of positivism) and John Stuart Mill observed that human life is affected by nonrandom variables such as heritage, volition, fortune, politics, and power; therefore, they argued, a bell curve is not an appropriate model for the social sciences.

The bell curve has helped establish conventional assumptions about what can be measured. If we want to produce a bell-curve distribution, we have to begin by identifying characteristics that display human diversity and then superimposing conventional dividing lines along continuums of difference (e.g., age, race, and gender) in order to demarcate discrete categories (just as we impose conventional dividing lines along the visible light spectrum to demarcate discrete colors). For example, many statistics textbooks use the example of height to illustrate normal distribution. However, height is not normally distributed in the general population; height is affected by nonrandom variables such as age, genetics, nutrition, and socioeconomic conditions. Measurements of height will display a bell-curve distribution only after we have first created particular discrete categories and then selected some categories, such as age and race, and dismissed others, such as class and blood type. Age-specific nutritional deprivation and adolescent growth spurt both affect height; however, nutritional deprivation and growth spurts have not generally been included as salient factors in height statistics because their inclusion would render a skewed curve instead of a bell curve (see A'Hearn, Perracchi, & Vecchi, 2009). In most social sciences, the bell curve comes first, and it then determines what is important to measure and what is not important. By these mechanisms, the bell curve influences assumptions about what counts as empirical.

In educational theory and philosophy, the key epistemological question is whether the bell curve should be regarded only as a display of probability functions for random continuous variables, or if it should also be used as a model of distribution for measurable things in the world.

What Counts as Normal

For much social science research, the bell curve underwrites definitions of normal in standards of measurement and research design. Quetelet's quantities were transformed in the 1800s to fabricate the Average Man; similarly, the bell curve has made it possible to fabricate the Average Student as the normal standard for designing curricular materials, assessments, and "best practices" in education. By determining what can be measured in empirical studies, the bell curve helps uphold conventions for classification and assessment. These conventions then serve as a precondition for defining average as normal and rarity as deviant. In education, this stance is reflected in the terms *normal distribution* and *exceptional children*.

Bell-curve thinking in education creates a tension between average as normal and average as mediocre. Average behavior is sometimes valued (as normal) and sometimes devalued (as second rate); exceptional behavior is sometimes valued (as excellence) and sometimes devalued (as abnormal). Bell-curve thinking defines normal as frequent and abnormal as rarity. However, non-bell-curve thinking makes it possible to define normal and abnormal according to ethical (or utilitarian, or political) criteria rather than according to frequency distributions.

Test Design and Discrimination

A random collection of test questions would not yield a bell-curve distribution of results; test items must first be carefully revised and strategically combined before results will yield a bell curve. In the process of developing tests, questions are first piloted to determine whether the tests measure what they are expected to measure. Ultimately founded on Quetelet's theological belief that empirical things of the world should be distributed in a bell curve, standardized test questions are considered to be valid when results produce a bell-curve distribution and a robust discrimination index (the level of precision in ranking made possible by a test item). New tests must be "normed," which means the test items are repeatedly revised until new tests reproduce the same bell-curve distribution that was established by previous versions of the test.

The bell curve is also a necessary component of IQ testing. Between 1908 and 1911, the French psychologists Alfred Binet and Theodore Simon invented a battery of tests called the Binet-Simon scale. In 1916, Lewis Terman published the Stanford Revision, which was based on a purposeful sample of 981 middle-class White nine-year-olds in California. Stanford researchers made several fundamental changes to the original Binet-Simon scale, one of which was to assume a bell curve as the basis for validating the test questions; by definition, half of all IQ test takers are assigned scores below 100, and half are assigned scores above 100.

The Stanford-Binet test also expressed IQ as a single number (which contravened Binet's earlier directives) and attributed IQ to inheritance rather than environment.

In their 1994 book *The Bell Curve,* Herrnstein and Murray maintained the Stanford assumption that intelligence is heritable. They also argued that variations in IQ scores among racial groups are evidence of genetic differences in cognitive ability and that differences in IQ cause social and economic inequality. Therefore, they argued, public policy should be based on an acceptance of a cognitive elite. The main arguments against Herrnstein and Murray's claims are that intelligence is not immutable, intelligence is not a single "g factor," the analysis confounds correlation with causation, and the premises are fundamentally racist.

The history of the bell curve suggests that the main purpose of IQ testing has been not to measure human characteristics but rather to establish social stratifications. Such stratifications are made possible because of the fallacious belief that the bell curve exists in nature.

BILDUNG

The philosopher Wilhelm von Humboldt (1767–1836) used what originally was the pietistic and theological term *Bildung* to refer to the humanistic ideal of self-cultivation and self-transformation. It is likely that he borrowed the term *Bildung* from the biologist Johann Friedrich Blumenbach (1752–1840), who claimed that all organisms possess a so-called *Bildungstrieb* ("drive of development"). *Bildungstrieb* refers to a force inherent in organisms—including humans—that has an implicit goal toward self-realization and self-perfection (*Vervollkommnung*). Such a biological view was most probably much more influential on Humboldt's thinking than the mystic or pietistic origins of the term. This entry reviews the evolution of this educationally important concept, from its initial elaboration in the era of the Enlightenment through successive phases of its development to its recent encounter with postmodern and poststructuralist currents in educational discourse.

Historical Background

It should be stressed at the outset that Bildung is not exclusively a German concept, as is sometimes stated in educational discourse. Rather, the topic of the educated mind is a central one in most educational theories and philosophies in various cultures, languages, and epochs. The idea of Bildung understood as human development and an end in itself can also be found in the Anglo-Saxon tradition of liberal education—but there are, of course, important differences with regard to the details.

Nevertheless, the German literature has been prolific; in it, the concept of Bildung refers to "the inner development of the individual, a process of fulfillment through education and knowledge, in effect a secular search for perfection, representing progress and refinement both in knowledge and in moral terms, an amalgam of wisdom and self-realization," (pp. 53–54) as Peter Watson (2010) tried to define it for an English-speaking community. German thinkers—for instance, Moses Mendelssohn and Johann Gottfried von Herder—identified Bildung with the Enlightenment, a view that might not be

obvious. It is important here to remember that the German Enlightenment (*Aufklärung*) came later in history than the French, English, and Scottish Enlightenments. The German *Aufklärer*—"men of Enlightenment"—could borrow from their neighbors and their achievements.

Whereas the idea of societal change was widely accepted in late-17th-century and early-18th-century Europe, the German Enlightenment specifically focused on the direction, logic, and meaningfulness of change. German intellectuals were fascinated by the French Revolution at first but later were disgusted by the postrevolutionary terror. To them, this was a remarkable backlash to the hope of political progress and freedom. In the early Western Enlightenment period, freedom was understood as an outward, definitely political concept; in the later German Enlightenment, in contrast, the predominant understanding of freedom was characterized by a rather aesthetic dimension: not outward but internal freedom. This shift from a political understanding of the Enlightenment—as in France, and also England or Scotland—to the German inwardness (*Innerlichkeit*), as realized in the concept of Bildung, can at least to a certain degree be interpreted as the desire of German intellectuals to escape from a brutal and on the whole disappointing postrevolutionary world to a place where humankind could seek secular perfection. It is not surprising, then, that today the notion of humanist Bildung is critically discussed not only as an aesthetic escape from a world in which political and juridical issues are urgent (an intellectualized refusal to adopt a political attitude toward the world) but also as a *secularized theology.*

The Notion of Bildung

Today's educational discourse in the German-speaking countries distinguishes between Bildung ("the acquisition and/or possession of formal, most of all academic, knowledge") and *Erziehung* ("upbringing and character development"). On the other hand, professional and academic development and support (training or vocational education) are usually called *Ausbildung* (see Winch & Gingell, 2008, p. 25). Whereas Erziehung is understood as intersubjective interaction and as a process of intentional influencing, the *traditional* concept of Bildung means self-formation or self-cultivation, and it is sometimes also understood as self-upbringing, that is, it refers to inner-subjective or subjectivating processes (see Schneider, 2012). The notion involves a reversal of the usual way of understanding oneself and the world; but in this context, the resistance of the world (or of experience) against this self-developmental process is—according to von Humboldt—considered to be highly significant (see Dörpinghaus et al., 2006, p. 71).

Bildung is considered to have an objective as well as a subjective dimension. The former refers to "culture" as a philosophical, scientific, aesthetic, or moral interpretation of the world, either referred to as *Allgemeine Menschenbildung* ("general human education") or as *Allgemeinbildung* ("broad educational experience"). The latter refers to the specific ways individuals acquire the objective content of culture. Indeed, it might be said that what groups of humans perceive as culture (whether ethnicity, national identity, community, etc.) is Bildung at the level of the individual. Jürgen-Eckhardt Pleines (1971/1989a) suggested a systematization of the educational meaning of the concept of Bildung that is still convincing today, knowing full well that a "premature determination of its meaning or a structural reduction of its original meaning will result in its decline and thus in the leveling of its originally intended contents" (p. 12). Pleines refers to Bildung (1) "as a valuable commodity which must be strived for," (2) "as a state of mind," (3) "as a process of mind," (4) "as a permanent task," (5) "as human's self-fulfilment in freedom," and, finally, as pointing to (6) the "educated ('*gebildet*') person and his/her Bildung of reason and heart" (pp. 12–38).

Recent Attempts at Reformulation

Since the mid-20th century, in the course of the broad establishment of the social sciences in the educational discourse, there have been efforts to replace the concept of Bildung by concepts such as deculturation, socialization, ego identity, development, and qualification. Thus, the concept of Bildung went through periods of trivialization and sometimes complete transformation. The ambiguity and vulnerability of the (original) concept of Bildung have nevertheless not resulted in the idea of Bildung being replaced satisfactorily by the surrogates that have been suggested. For instance, Hansmann (1988) demonstrated convincingly how each of the claimed theoretical equivalents, such as scientific orientation, socialization, qualification, Erziehung ("upbringing"), or teaching, fail to go into sufficient depth.

Insightfully, Friedrich Schweitzer (1988) also argued against equating (ego) identity and Bildung.

It must not be overlooked, here, that the term can be defined only in what has sometimes been called a cumbersome way, possibly "because the idea of Bildung is an essentially social idea, thus having different meanings according to the various customs and interpretations" (Musolff, 1989, p. 9). Thus, following H. Posner (1988), it might have to be accepted that "Bildung, one of the crucial terms of philosophical anthropology and education . . . [is] at the same time one of the most blurred ones" (p. 23). Wolfgang Brezinka (1972) went even further and called the term "almost empty" (p. 62).

In the 1980s, after having gone through something of a crisis, Bildung experienced a renewed boom, maybe precisely because of the social challenges the educational sciences were actually confronted with in those days and which have escalated since. The revitalization of the concept of Bildung as a result of the changes triggered by an "ever more radicalizing modernity" does not mean that its history can be left behind. This is not the place to speculate about the reasons for this revisitation and for why the concept is discussed even by political authorities (see Posner, 1988). It may simply be stated that the concept of Bildung has both experienced a renewal of significance and become even more difficult to grasp.

An essential aspect of Bildung is the idea, explicitly or implicitly shared by the various ways of understanding it, that it is a mediator between the "unity of the individual" and the "totality of the world" (Posner, 1988, p. 26). One may imagine this mediation as a process, a state, or a goal. The ideals of educational objectives (responsibility, independence, self-determination, reasonable practice, etc.) thus provide the concept of Bildung with its "typical dignity" and make it a regulative idea of general education and educational theory—"a place of normative understanding within it" (Miller-Kipp, 1992, pp. 18–19). In whichever way the term is used, the point remains that the actual referent of the concept of Bildung is the subject as a self-educating individual or an individual undergoing education. Thus, educational theory cannot avoid questions concerning the constitution of the subject—not only in the philosophical but also in the psychological and sociological sense.

Whereas Bildung as self-cultivation and an end in itself is certainly not a constitutive idea of the (empirical) description of education and educational processes, the question remains whether it still has the power (or should have the power) to function as a regulative idea in modern societies. The latter are strongly affected by instrumentalist and pragmatist worldviews that provide seemingly convincing tools to approach practical problems and decision-making processes, especially in the domain of education. Nevertheless, it is the very lack of humanistic regulative ideas in educational discourse that seems to be the source of the widespread feelings of malaise and even crisis in modern education. As economic rationality continues to colonize the *Lebenswelt*, or lifeworld, the humanistic and modern project of moral betterment, both of the individual and of humankind, is at stake. For more than 20 years, there have been attempts to radically question the concept of Bildung from a poststructuralist and postmodern point of view, but there have also been—and will continue to be—attempts to transform it (see Masschelein & Ricken, 2003).

Bilingual Education

Bilingual education can be broadly defined as a program that employs more than one language as the medium of instruction for the curriculum. It may be distinguished from foreign-language or second-language education, in which proficiency in the language is the goal and the curriculum is organized around the attainment of various levels of proficiency in the foreign or second language rather than in the content areas across the curriculum (e.g., math, science, and literacy).

The rationale for delivering instruction bilingually can vary significantly and depends on a wide variety of social, political, and historical circumstances related to the status of the language and its speakers. During periods of ethno-linguistic pride asserted by language minority groups, bilingual education may serve as a symbolic point for the linguistic rights of minorities. During periods of heightened interest in foreign economic competitiveness or a heightened sense of national security, bilingual education may become an instrumental means for students to develop high levels of proficiency otherwise unattainable through traditional foreign-language programs. In societies where bilingualism (or multilingualism) is official, such as in Canada or Switzerland, bilingual education may become an instrument through which the recognition of the languages is politically negotiated between the officially recognized ethno-linguistic groups.

Typically, immigrant languages have less prestige, and during times of linguistic nationalism, the recognition of nonmajority languages through bilingual education becomes an object of symbolic politics. The English-only movement in the United States, for example, has seen bilingualism in any form—bilingual education, bilingual ballots, bilingual social services—as incompatible with the unifying forces of an official language, and the movement has used the label "bilingual" as an instrument of wedge politics. Indigenous languages may carry the weight of incumbency in the territory, but the act of recognizing indigenous languages is complicated by the history of invasion and occupation by the majority language, making it different from the recognition of immigrant languages.

In the United States, bilingual education often serves as a transitional program in which the native language of the immigrant or language minority group is used as a crutch while students are given time to learn English. These programs, however, do not support development in the native language once the students have learned enough English to survive in the monolingual environment. An alternative approach is one that values the native language and attempts to maintain it. Maintenance bilingual programs continue to develop literacy in the native language, and in the case of dual-immersion programs, native speakers of English whose parents value, and wish their children to learn, the language

of the immigrant community participate, so that the bilingualism is developed in both directions.

The effectiveness of bilingual education programs is difficult to evaluate because the educational goals vary significantly—for example, proficiency in the two languages may be a key goal of some programs, but others, such as the French immersion programs in Canada, are keenly concerned about demonstrating that the Anglophone students participating in these programs are not losing ground in their academic achievement as measured in English. Others, such as bilingual programs in the United States, are mainly concerned with equitable attainment of academic achievement by nonnative speakers of English compared with monolingual English speakers, as measured through English tests. In general, it is safe to conclude that well-implemented bilingual education programs attain their specific objectives but that the outcomes vary considerably depending on the background characteristics of the students who enroll in these programs. Favorable outcomes are more often found among middle- and upper-class students.

Guest-worker programs, such as bilingual programs for the children of Turkish workers in Germany, provide an additional angle on bilingual education. In these programs, the ultimate motive for supporting the home language is to enable a smoother return to the home country for the students and their families. The concern is the rapid shift that might otherwise occur even among the guest-worker communities, where the dominant language becomes the language of the host country.

Second-Language Acquisition and Instruction

The nature of language is central in how second-language acquisition is supported in bilingual education programs through the curriculum, the instruction, and the training of teachers. Linguists analyze language in terms of its phonological, morphological, syntactic, semantic, pragmatic, and sociolinguistic properties. Second-language acquisition seen as developing knowledge of a set of rules (e.g., how past tense is marked) or developing a set of educational practices (e.g., constructing an explanation) will result in vastly different curricular arrangements and expectations for teacher knowledge about language.

A related issue is how explicitly various aspects of language need to be addressed in the curriculum. A question that concerns practitioners is whether or not to dedicate specific time in the curriculum to the various analytic aspects of language or whether these aspects of language can develop naturally and incidentally in the course of academic content instruction—for example, learning the language during math and science instruction.

Sources of Variation in Second-Language Acquisition

Researchers in the development of bilingualism have investigated a number of hypotheses about individual variability in the outcomes of second-language acquisition. These include the age of the learner, socioeconomic background, language status, learner personality, and learner motivation.

The most discussed is the age of the learner. In its boldest form, this can be stated as a hypothesis about a biologically founded critical period for second-language acquisition. This hypothesis would imply that before a certain age (often somewhere between the ages of 5 and 15), the second language is learned quickly and automatically, using mechanisms similar to what was available for learning the first language. After the critical period, learning can only be achieved through alternative mechanisms. Although appealing, this hypothesis finds little support. The most carefully conducted research shows an age-related decline throughout the life span and no documentation of dramatic differences between those before or after a proposed critical period.

Socioeconomic background, including the home literacy levels of the students, provides another important source of differences between students. Programs that appeal to middle-class students show stronger outcomes than those for lower-class students, and even within programs, student home background is a strong predictor of ultimate learning among the students. These data track the general findings of educational outcomes related to social class.

Individual psychological factors such as personality, motivation, and social psychological variables have been investigated extensively within foreign-language programs, but less so within bilingual education programs, with the exception of Canadian bilingual programs, where they have shown predictive power in student learning outcomes.

Benefits of Bilingualism

An aspect of bilingualism often overlooked by educators is the potential benefits of bilingualism on

some specific aspects of cognition, including metalinguistic awareness, attentional control, and executive function. Bilingual children show advantages on a variety of tests of psychological functioning in these areas over comparable monolingual children. In addition, there is emerging evidence from hospital records for the substantial delay of onset of dementia for bilinguals. Thus, in addition to the direct linguistic and educational benefits of bilingual education, there is emerging evidence of the long-term health benefits of bilingualism. Although the research is still far from pointing to specific educational interventions that might result in bilingualism, it suggests that the field of bilingual education has prospects that extend well beyond a compensatory framework of bilingualism to a far-reaching vision embracing people's longevity and mental acuity.

Bruner, Jerome

The psychologist, philosopher, and pragmatist Jerome Bruner (b. 1915) has borne witness to the wide-ranging and wild enthusiasms of the field of psychology—behaviorist, cognitivist, cultural, developmental—for more than 65 years. Repeatedly, he has played important roles in authoring and critiquing his field (including his own earlier work), fearless in his embrace of the complexity of the human condition and vigilant in considering how social science can shape and be shaped by important social issues. His research included work on how people process information and on the early development of spoken language. This entry discusses the breadth of Bruner's research, his political involvement in education, and his influence on psychology and education.

Born in New York City, with degrees from both Duke University (BA, 1937, Psychology) and Harvard University (MA, 1939; PhD, 1941, Psychology), Bruner has held positions at Harvard, Oxford, the New School of Social Research, and New York University. His oeuvre includes 20 books on topics ranging from cognition and learning, to knowing and meaning, to narrative and language, to education and law. *The Process of Education* (1963), his summary of a summit meeting of leading scientists and social scientists drawn together to respond to the "missile gap" crisis in the wake of Russia's launch of Sputnik, the world's first artificial satellite, has been translated into 21 languages. Drawing widely on disciplinary tools from anthropology, psychology, linguistics, and literary theory, and consistently embedding himself within interdisciplinary communities, Bruner has always exhibited an *esprit de finesse*—the ability to hold together a number of elements in nice balance—understanding that an infinite range of factors, known and unknown, shape the human condition (Geertz, 1997).

Bruner started his career at Harvard with a study of the "helplessness" of imprisoned rats. He quickly became part of the generation of psychologists in the 1950s who brought the mind back into the discipline "after a long cold winter of objectivism" (Bruner, 1990, p. 1). Rejecting studies of stimuli and responses, Bruner and his colleagues were taken with understanding how people reason, feel, imagine, and know. As cognitive studies—a field he helped create—grew, Bruner became a strong critic of how cognitive "science" had—ironically enough—dehumanized the mind, virtually estranging psychology from the arts and humanities.

In response, Bruner eventually helped lead a "cultural" revolution within psychology, drawing heavily on anthropology and arguing that the mind is not "programmable" but rather is a social and historical achievement. In his own research, Bruner sought to understand how language develops (especially among the young) and how cultures shape the

mind. Central to this has been his work on narrative and how cultures and individuals use stories to shape their own and others' lives. Bruner has been honored with 25 honorary degrees, a Festshrift (Olson, 1980), a volume of essays on his philosophy (Bakhurst & Shanker, 2001), and the International Balzan Prize (in 1987); he is a fellow of the American Academy of Arts and Sciences.

Major Themes

In the 1950s, Bruner was one of several early leaders of psychology's cognitive revolution. Instead of focusing on stimulus and response, and operant and classical conditioning, Bruner and his colleagues—Ulric Neisser, Donald Broadbent, George A. Miller, and Noam Chomsky among them—sought to describe how humans made meaning from their encounters with the world. Based on earlier empirical work that he had done on children's perceptions, Bruner supported a "New Look" psychology that focused on humans' interpretations of events and objects, rather than simply documenting their observed responses to stimuli. In *A Study in Thinking* (Bruner, Goodnow, & Austin, 1956), Bruner and his colleagues reported on a series of groundbreaking studies on human concept formation and inductive reasoning, and the work is considered a classic in the so-called cognitive turn in psychology. Shortly afterward, Bruner and Miller founded Harvard's Center of Cognitive Studies, which became a leading think tank for interdisciplinary teams of anthropologists, linguists, historians, philosophers, and psychologists who were documenting how humans make meaning.

By his own account, Bruner's (2006a) interest in education arose in the 1950s as he witnessed the "desperate ideological struggles" of the time. When Sputnik was launched, concerns about science education rose, with U.S. policymakers arguing that the "missile gap" between the Soviet Union and the United States was a national, political, and intellectual threat. The National Science Foundation responded, supporting numerous curriculum development projects that involved research scientists and mathematics around the country. Bruner, who had been pulled into helping Jerrold Zacharias at MIT (Massachusetts Institute of Technology) with his Physical Science Study Committee work, was invited to cochair (with Zacharias) a meeting convened at Woods Hole, Massachusetts, in which the investigators on these projects deliberated about curriculum, the role of cognitive psychology in education, and the future of mathematics and science education. This led to one of Bruner's most important works, *The Process of Learning*, and later to his work on the development of the controversial social studies curriculum, *Man: A Course of Study* (MACOS). MACOS, which was based on Bruner's idea of a "spiral" curriculum, was a humanities program meant to teach students about the life spans of living things—from salmon to reindeer to humans. The curriculum was designed to provoke students to ask questions, including questions about morality. Fundamentalist groups, in particular, raised rancorous objections, as documented in the film *Through These Eyes* (2004). Not one to shy away from controversy, Bruner became increasingly aware of the political currents that swirl around educational initiatives. His baptism by fire through MACOS appears to have only deepened his commitment to proactively engage in the politics of education: Throughout the 1960s, he served as a member of the Educational Panel of the President's Science Advisory Committee to both Presidents Kennedy and Johnson.

Bruner's interests in cognition and meaning making then led him to investigate the conditions for the early development of spoken language. His research convinced him that young children are powerfully proactive in their own learning and capable of developing conceptual powers at a young age. That work also taught him the damaging effects of poverty on early mental development. As a consequence, he was among the social scientists who argued for what became the Head Start program. While his own work led him to chafe at the "deprivation" theory that animated some of the federal Head Start work, Bruner was vehement in his conviction that poverty was the enemy of young children's minds.

In the 1970s, Bruner continued this empirical, theoretical, and political work in Great Britain, where he taught at Oxford and teamed up with colleagues, including Harry Judge, to work in the Preschool Research Group and later with the Preschool Playgroup Association. Here too, social scientists and humanists investigated young children, language, and development and worked to persuade the then minister of education, Margaret Thatcher, of the critical role of preschools in young children's development. As had been the case in the United States, while at Oxford, Bruner swam in the broader intellectual currents of the time, most notably the linguistic turn in Oxford philosophy, which led him to reconsider how communicative intentions

shape language use and structure. The combination of theoretical and empirical work shed new light for Bruner on how cultures shape the mental development of their members, including children. This work eventually led to the "cultural" revolution in psychology, a shift that pressed for a conception of the self that acknowledged how our selves are not "isolated nuclei of consciousness" but instead are constructed by society and history (Bruner, 1990).

On returning to the United States in the 1980s, Bruner moved back to New York City, where he joined the faculty of the New School for Social Research and later the faculty at New York University, where he is currently a member of both the Department of Psychology and the School of Law. Drawing again from broader intellectual currents, he then used the writing of authors like Julian Barnes, Milan Kundera, and Jacques Derrida to consider the role of narrative in meaning making. Bruner (1996) became convinced that human beings "live in a sea of stories" (p. 147), most often authored by the cultures in which we live. His recent work (e.g., Bruner, 2003) explores how we learn through the stories we tell and are told.

A restless thinker, play has always been an important theme in Bruner's work. He saw play as a way to tap into our cognitive powers and rethink possibility. This playfulness has led him to ignore boundaries—between conceptual and empirical work and between disciplines and fields of study. He has been, at once, an intellectual—trying on ideas from across fields, ever vigilant about the limitations any scholar faces in explaining something as complex as the mind and how one constructs meaning or learns—and an activist/teacher, whether proposing theories of instruction, creating curricula, or arguing for programs like Head Start. And the stories Bruner has told us—about the mind, about children, about teaching and learning, about narrative and culture—have shaped contemporary psychology and education in profound ways.

Buber, Martin

Martin Buber (1878–1965) was a prominent 20th-century philosopher, Jewish religious thinker, and cultural Zionist whose well-known distinction between I–Thou and I–It relations formed the basis for a unique philosophy of education, with distinctive conceptions of learning for meaning, teacher–student relations, and the role of education in the cultivation of community. In addition to its impact on Jewish thought and education in Israel and abroad, Buber's philosophy of dialogue exercised considerable influence on Nel Noddings's (1984) ethics of care, Emmanuel Levinas's (1998) ethics of responsibility, and the work of Protestant theologians such as Paul Tillich (1948, 1952).

Born in Vienna in 1878, Buber was raised by his paternal grandparents in Lemberg (Lvov). His grandfather, Solomon Buber, was an important Jewish communal leader and scholar who edited the first critical edition of the traditional rabbinic biblical commentaries. Martin was educated in Vienna, Leipzig, Zurich, and Berlin, after which he was appointed the first lecturer in Jewish Religious Philosophy and Ethics at the University of Frankfurt, where he taught until 1935, when he accepted a chair in Social Thought at the Hebrew University of Jerusalem. He is best known for his 1923 classic

I and Thou (*Ich und Du*) and a series of influential works on the philosophy of dialogue, but he also published extensively on the Hebrew Bible, which he translated into German with his colleague Franz Rosenzweig, and the modern Jewish mystical sect known as Hasidism, from which he drew inspiration for his dialogical thought. Buber died in Jerusalem in 1965.

According to Buber (1970), life's meaning and purpose are discovered in moments of I–Thou, or subject–subject, relation—in which one receives another into oneself for the sake of meeting as an end unto itself—but they are implemented through I–It, or subject–object, relations—which are maintained for utilitarian purposes. Whereas subject–subject relations cannot be contained within rules or formulas, subject–object relations are so constrained. Indeed, any attempt to express the pure encounter of an "I" with a "Thou" in rituals or laws already transforms the meeting into an instrumental relation. God, in Buber's view, is uniquely and "eternally Thou," to be glimpsed in the meeting of one subject with another. Encounters of this kind transpire not only between people but also between people and texts, objects, natural settings, musical pieces, and artistic creations.

The Hebrew Bible, the prophetic tradition in particular, records just such an encounter between God and the people of Israel, and the mystical tradition in Judaism represented by Hasidism constitutes an especially authentic representation of the divine–human encounter (Buber, 1958). In contrast to many orthodox interpretations of Jewish tradition, Buber held an antinomian view of religion believed to share much in common with Protestant Christianity, especially as interpreted by the likes of the existentialist theologian Paul Tillich (1952). Buber (2003) held, however, that the Hebrew Bible grounds faith in mutual trust between God and human beings whereas Christianity places greater emphasis on specific beliefs about God, that He exists, for example, or took a human form as Jesus of Nazareth, who suffered and sacrificed Himself to redeem humankind from sin.

Buber (1963) translated his religious existentialism into a utopian political theory called Hebrew humanism, tied closely to his Zionist convictions. In this view, the return of the Jewish people to the land of Israel offers a unique opportunity to reinvent the sort of political community envisaged by the Hebrew Bible, grounded in the qualities of dialogue and mutuality that he saw in Hasidism. The kibbutz movement of collective farming villages, which mixed socialism with a drive to connect physically to the land of Israel, is a good example of such a utopian community. Similarly, he envisaged the State of Israel as a binational state in which Jews and Arabs would live in peaceful coexistence grounded in mutual respect and dialogue (Buber, 1983).

Buber (2002) also made important contributions to educational thought. In his inaugural lecture at the opening of the Lehrhaus Judaica in Frankfurt in 1920, Buber extended his distinction between subject–subject and subject–object relations to the curriculum by distinguishing between *Lehrnen* and *Lehrnstat*. The former engages matter to be studied as a subject for encounter, to be incorporated into one's being as a source of value and direction, while the latter formalized information as an object, for the purpose of the discovery or construction of knowledge. Instruction in modern schools and universities has tended to emphasize the latter; the Lehrhaus, which he launched with Franz Rosenzweig as an updated rabbinic house of study, would cultivate the former (Rosenzweig, 2002). This subject–subject pedagogy requires a distinctive relation between teachers and students grounded in dialogue. However, as Nel Noddings (1984) would later emphasize in her "ethic of care," teacher–student dialogue is not completely mutual; the teacher gently guides the student in ways that need not be reciprocated, confirming his or her more elevated qualities along the way. An education grounded in *Lehrnen*, in which teachers confirm the ability of their students to develop into unique people in their own right, is essential to the sort of utopian community that Buber envisaged.

Buber's Jewish and philosophical positions were criticized on a number of grounds. Gershom Scholem (1937), who founded the academic study of Jewish mysticism, argued that Buber overly romanticized Hasidism and underestimated the power of divine commandment in Jewish mysticism. The Modern Orthodox theologian Elieser Berkovits (1962) extended this critique to Buber's antinomian account of religious law altogether, and Walter Kaufman (1983), who translated *I and Thou* into English, similarly suggested that Buber's conception of relation mistook "deep emotional stirrings for revelation." Franz Rosenzweig (2002) asked why it is impossible to encounter religious practices in dialogue, since Buber held that we can meet texts, nature, music, and art in this way. Surely, Rosenzweig reasoned, we should be able to transform objective

laws (*Gesetz*), which derive their extrinsic authority from the divine, into subjective commandments (*Gebot*), in which the call to observe is heard intrinsically, from within. Finally, the phenomenologist Emmanuel Levinas (1969, 1998) challenged the role of mutuality in Buber's conception of dialogue, arguing that in relation one has an absolute obligation to accept responsibility for the other regardless of whether or not this attitude is reciprocated by the other toward oneself.

Capability Approach: Martha Nussbaum and Amartya Sen

The capability approach (also known as the capabilities approach) is a theoretical and normative framework concerned with well-being, the just design of institutional and social arrangements, poverty, and human development. The approach was originally pioneered within political philosophy and welfare economics by Nobel laureate Amartya Sen and was further developed by the philosopher Martha Nussbaum and, more recently, by many other scholars.

During the past three decades, the capability approach has influenced a wide range of academic research, including philosophical theories of social justice and the domains of social policy and development studies, as well as the work of international agencies, for example, the United Nations Development Programs and Reports. The approach has also increasingly informed studies in education with a particular focus on questions of educational justice, disability and special-educational needs, gender, and access to higher education. The reach of the capability approach is therefore broad and interdisciplinary and covers both theoretical and practical domains of inquiry.

As a theoretical and normative account, rather than a full-fledged theory, the approach provides a conceptual framework for defining the individual's well-being and a normative position on how just social and institutional arrangements *ought to be* designed. More specifically, the approach contends that well-being should be conceptualized in terms of individuals' capabilities to achieve valued functionings and thus to lead the kind of life they value. Functionings consist of all the beings and doings that people have reason to value, or, in other words, they are states and actions that make one's life valuable. Functionings are countless, from simple ones, such as being rested, being happy, or being thirsty, or reading, listening to music, or cooking, to more complex ones, such as being a foster parent, participating in the life of the community, or working as a librarian. Capability refers to the real, effective opportunities that people have to choose among valued functionings; hence, they are the real freedoms to be and to do what one chooses and values. The normative core of the capability approach is that individual well-being, as well as social arrangements and policies, should be evaluated in terms of capability, thus in terms of the effective freedoms and opportunities to choose among valuable kinds of lives.

While capability and functionings are the core concepts of the approach, Sen and Nussbaum have developed different versions of the framework. Whereas Sen has primarily focused attention on questions of justice, freedom, and poverty, Nussbaum has given the approach a universal scope by specifying a list of central human capabilities that, in her view, characterize what makes a life truly human. These differences are worth exploring in more detail.

Sen's Approach

Sen originally devised the capability approach as an innovative account of well-being, both for welfare

assessment and for theories of justice. He proposes the approach as an alternative, on the one hand, to the utilitarian view that defines well-being in terms of utilities, or preference satisfaction, and on the other, to John Rawls's position on justice as fairness, which evaluates individuals' relative advantage by assessing their holdings of social primary goods, that is, resources such as income and wealth. According to Sen, rather than concentrating on subjective states such as satisfaction or on the resources that people have at their disposal, any account of justice should focus on what people can be and can do with their resources to achieve well-being. In his view, well-being lies in the real freedoms, the effective capability that people have to achieve chosen functionings; and, therefore, just institutions should seek to equalize people's capability, or their effective opportunities to lead valuable lives. Sen further specifies some basic capabilities that are essential to well-being, such as being nourished and sheltered, being educated and healthy, and appearing in public without shame.

In Sen's view, the lack of the relevant basic capability determines disadvantage and inequality, and poverty is therefore seen as a failure of capability. Thus, while fasting is a valued and chosen functioning for some and may lead to well-being, starving is the absence of the relevant capability—that is of the relevant freedom to achieve the relevant functioning, in this case being nourished.

In addition to the centrality of capability for justice, Sen also introduces a very important element in the evaluation of individuals' relative positions: the concept of human diversity. Sen maintains that differences such as personal, physical characteristics and climatic and environmental factors, as well as cultural and social elements, should all be accounted for when evaluating relative disadvantage. These constitutive features of human diversity, in Sen's view, lead to a different conversion factor of resources into well-being, and as such, they should be included in the evaluative process. A conversion factor is the degree to which a person can transform a resource into a functioning. These factors can be personal, social, or environmental. For example, to function adequately in her environment, a pregnant woman living in a cold climate will require a different amount of food from the amount required by a nonpregnant woman living in the same environment, other things being equal. Her pregnancy, the environment, and specific policies providing nutritional supplements are factors that affect the extent to which a diet high in nutritional value will contribute to her well-being.

Despite his attention to questions of justice, Sen has not further specified what capabilities should be promoted through the design of social and institutional arrangements. He maintains that any list of specific capabilities must be the result of a democratic process of deliberation involving all the relevant parties, that is, all those who will be affected by the decision. In this sense, Sen's version of the capability approach is intentionally unspecified.

Nussbaum's Approach

Nussbaum's capabilities approach has provided a different, and to some extent more specified, version of the framework. Nussbaum endorses the concept of capability as the variable for comparisons of well-being and freedom, but she identifies a list of 10 central human capabilities, which governments should secure to all individuals up to a certain threshold level of adequacy as a constitutional guarantee. These capabilities include life (including the ability to live a life of normal length); bodily health; bodily integrity (the ability to change locations and to have sovereignty over one's body, including not being vulnerable to assault); the ability to use one's senses, imagination, and thought; emotions, including attachments to things outside ourselves; practical reason (the ability to form and revise a conception of the good and a life plan); affiliation (the ability to form and engage in meaningful relationships); the ability to play; the ability to have concern for other species; and control over one's material and political environment.

The capabilities of practical reason and affiliation are accorded primacy as they support and allow the development and exercise of all the other capabilities. Moreover, Nussbaum specifies her central capabilities as "combined capabilities" that result from the combination of internal capabilities with suitable external conditions for the exercise of functionings. Internal capabilities are developed powers of the person, such as the capability to speak or to form a political opinion. These internal powers can only become functionings when the external conditions are favorable to their enactments. For example, a person may have the capability of forming and expressing an opinion but might be prevented from exercising it by oppressive regimes.

Nussbaum contends that her central human capabilities have a universal dimension. She maintains

that each capability in the list expresses a fundamental aspect of a life lived with the dignity of a human being and, as such, her list can be recognized as essential for well-being by people who otherwise endorse very different conceptions of the good. She further contends that her list can therefore be considered the product of a political process of overlapping consensus. Nussbaum does not provide any further articulation of her claim, but she insists that her list of central capabilities provides the basis for an adequate social minimum that governments have to deliver as a matter of justice to all individuals. In other words, government should secure the achievement of a threshold level of functionings for each capability. In her more recent work, Nussbaum has extended her analysis to questions of justice concerning people with disabilities, justice for nonhuman animals, and global justice. Overall, her version of the capabilities approach, in endorsing a minimum threshold level of capabilities that should be achieved by all human beings, can be considered a partial and minimal account of a theory of social justice.

Criticisms of the Capabilities Approach

The capabilities approach provides a new perspective on questions of well-being, justice, and poverty. However, while the approach has gained increased recognition in academic and policy arenas alike, it is not without its difficulties. Among others, two are worth mentioning. First, the approach is not a full-fledged theory, and as such, many theoretical and normative elements are in need of further specification—for example, the questions of what capabilities should be chosen and, if threshold levels of achievement are identified, what the requirements of justice are beyond them. Second, since the approach is intentionally open, the question about what is needed to develop a full capability theory of justice needs further exploration. Notwithstanding these limitations, the approach advances our understanding of well-being and freedom in significant ways.

Capital: Cultural, Symbolic, and Social

Capital is the central concept in the research tradition developed by the French sociologist Pierre Bourdieu (1930–2002) and his collaborators. In the period since this concept was forged during the 1960s, it has become widely used in virtually all branches of the social sciences and humanities. Capital in Bourdieu's sense denotes certain kinds of assets or resources—namely, those that gain social recognition. Take, for example, a PhD degree from an esteemed site of learning. To function as capital, this degree has to be recognized, in both meanings of the word: It has to be recognizable—all concerned have to be able to identify it—and its value needs to be acclaimed. (This is the case with doctoral degrees within the scientific community and in many other contexts in most societies, although this has not been the situation always and everywhere—in China in the days of the Cultural Revolution, for example, such a qualification probably was a handicap!)

Bourdieu differentiated between various species of capital. *Symbolic capital* is the most general concept. Any kind of asset—titles, know-how, material belongings, whatever—functions as symbolic capital if and only if it is ascribed value. This is true also for *economic capital*—made up not only of income, fortune, and material possessions but also of proficiency in mastering the private economy and comprehension of the world of finance; to be a form of capital, these things must be valued. *Cultural capital* is, alongside economic capital, the most powerful and effectual kind of asset at least in societies within the Western sphere of influence. In France

and similar countries, key components of cultural capital are familiarity with high culture and sophisticated skills in speech and writing, capabilities that are predominantly inherited from an upbringing in the upper social classes and also acquired in elite schools. *Social capital* is what makes it possible to profit from family bonds and contacts with friends, acquaintances, or old schoolmates. In addition, there are numerous more specific species of capital: educational capital (measured by, e.g., degrees), scientific capital (repute in the learned world), and so on.

Cultural Capital: The Classical Studies

Among educational theorists, Bourdieu's most well-known concept is probably cultural capital. While the term *cultural capital* was not introduced in Bourdieu's published writings until 1966, the concept was already very important in his first studies on the French educational system during the early 1960s, though at that time it was designated by other words: *cultural heritage*, *social heritage*, *cultural privilege*, and *cultural level*. It was originally used to explain the finding that variations in educational achievement among children from different categories of families could not be traced back solely to differences in economic conditions. Even more decisive in determining a successful trajectory through the education system were other resources in the parental home, especially the parents' educational level, mastery of the French language, and familiarity with the fine arts, together with all the other fine-tuned distinctions in the lifestyle and social conduct of the upper social classes. These kinds of symbolic possessions were labeled cultural capital. In a meritocratic society such as France, cultural capital is to a large extent sanctioned and transmitted by the education system. Therefore, in empirical research, the education achieved by individuals or groups—its character and its length—is frequently used as a rough indicator of the amount of cultural capital at their disposal.

In France, the book titled *The Inheritors* made Bourdieu famous almost overnight when it was published in 1964. Those "inheritors" were university students in the humanities faculty who tried to make themselves heirs of the assets that Bourdieu was later to label "cultural capital." Most of them had been equipped at home with a more or less solid cultural heritage that served as a precondition for smooth adaptation to the demands of the university. Those less well furnished had, with few exceptions, been already eliminated at lower levels of the school system. Besides selecting and rejecting different categories of the rising generation according to their possession of inherited cultural capital, the education system is also in itself the main site for the reproduction, legitimization, and transfer of cultural capital.

If these observations seem trivial or self-evident today, it is thanks to the seminal investigations by sociologists, especially in the 1960s. At the time, Bourdieu's conception of the educational system was highly controversial; the predominant view was what he described as *l'idéologie du don*—the ideology of the gift and the giftedness, namely, that schools and universities distributed their rewards according to the students' talents, regardless of social characteristics. The book on the inheritors made Bourdieu not only famous but infamous; he has testified that after its publication, former colleagues and teachers stopped greeting him when they met in the street.

Although originally developed to answer questions within the sociology of education, the concept of cultural capital also offered a key to understanding the structure of society as a whole. In contemporary sociology, social differentiation was commonly depicted as a vertical ladder with the rich at the top and the poor at the bottom. In works such as *Distinction* (1979), Bourdieu and his collaborators introduced a multidimensional understanding of the French "social space." Besides the vertical social hierarchy—with "the dominant class" at the summit, "the popular classes" at the base, and "the middle classes" in between—they did research on oppositions that stretched in other directions. Most important was the horizontal polarity separating groups holding more economic than cultural capital from those holding more cultural than economic capital. Thus, the dominating class consists of two main opposing factions: on the one hand, groups with abundant economic assets and economic power—owners and executives of big corporations and the like—and on the other, culture producers—university professors and others whose positions were based mainly on the possession of cultural capital. Two corresponding poles were found within the region of the middle classes: owners of small businesses versus librarians and schoolteachers.

Definitions of Cultural Capital

In the studies of French society, and subsequently in many other countries within the Western realm,

Bourdieu and his followers were able to identify cultural capital as the species of capital that is recognized throughout the entire society, by all social groups. It is especially appreciated among members of the dominating class—where it is also concentrated—but the lower ranks of the social hierarchy are aware of the supremacy of the legitimate cultural capital as well, although they might dislike it and realize that it is not available to them.

Of course, the content of cultural capital varies over time and from society to society. In the classical studies in the 1960s and 1970s by Bourdieu's team in France, it was found to be centered on highbrow culture, proficiency in spoken and written French, and other assets that were sanctioned and transmitted by the most prestigious schools. The content has changed since then. Not even in France does the mastery of Latin and Greek any longer constitute a principal component of cultural capital.

A simple way to trace the content of cultural capital is to ask the following question: "If in spite of limited economic means, you hold some kind of acknowledged position in society, what assets of yours entitle you to that position?" Those assets might be called cultural capital, at least in societies within the Western hemisphere. In very different kinds of societies, the most powerful noneconomic species of capital might instead be political, religious, or military.

An alternative definition is historical. Symbolic capital has existed in all places and at all times, wherever human beings share a perception of certain skills, capacities, or belongings as marks of honor, prestige, reputation—words that Bourdieu used in the late 1960s before he settled on "symbolic capital." With the expansion of writing techniques and the establishment of an education system, a new species of symbolic capital emerged—cultural capital. It was more stable and more transferable across regions of society and across generations since it was no longer necessarily attached to certain individuals or groups but could be objectified, as, for example, in documents, and institutionalized, as in titles and exams.

Social Capital

Individuals and groups do not only possess capital of their own. A wider array of resources is available among their relatives, friends and acquaintances, alumni from their old school, and other personal networks. "Social capital" denotes this repository of potentially available assets ready to be activated when required. If you are rich in social capital, you might be able to receive advice from a nephew working in the banking business when you consider taking a mortgage loan; and when in doubt about what school to choose for your children, you might call a former classmate who has ended up in the National Board of Education.

As in the case of cultural capital, the concept of social capital likewise emerged as a hypothesis to explain the findings in the early studies on education by Bourdieu and his collaborators. Even individuals equipped with similar holdings of inherited cultural and economic capital and comparable school achievements might meet with quite different fates in higher education and professional life. One reason for the success of some and the failure of others seemed to be differences in their social capital. For example, some had access to precious contacts, while others had to settle for the student counseling and employment services.

Social capital in Bourdieu's sense should not be confused with other notions with the same name. "Social capital" as introduced by the North American sociologist Robert Putnam in the 1990s is a different concept; it refers to the societal glue created by the networking of individuals at the grassroots level, which was supposed to foster cohesion, democracy, and economic development—individuals without such networks were said to be "bowling alone."

Fields and Field-Specific Capital

Most of Bourdieu's other key concepts are related to the concept of capital. *Habitus*—systems of dispositions that allow people to act, think, and orient themselves in the social world—might be regarded as a form of embodied or incarnated capital.

Another essential concept is *field*, introduced in a few theoretical texts by Bourdieu around the year 1970 and subsequently used in a steadily increasing number of historical and empirical studies from his research center. If we keep to the so-called productions fields, each of these is defined by its own "field-specific capital." The literary field—explored in *The Rules of Art* (1992)—is the site for the production and endorsement of literary values. The bearers of literary capital are recognized authors, together with critics, editors, and others to whom the field gives the authority to pass judgments on literary quality—and on authors.

In the same manner, the scientific field constitutes its own scientific capital. As shown in *Homo Academicus* (1984), there are also other species of capital at stake in academia, associated with, for example, administrative academic power, the industry's commercial concerns, or the agendas of the mass media or the political field. However, provided that the scientific field is autonomous enough, it controls its own mechanisms for the consecration of the most prestigious research achievements (and researchers), the selection of acceptable new entrants and the rejection of the rest, and the allotment of rewards and penalties—all of this based on the distribution of scientific capital.

The *field of power* is the system of relations between all important species of capital in a society, including the economic, juridical, political, bureaucratic, scientific, and artistic. In *State Nobility* (1989), Bourdieu and Monique de Saint Martin demonstrated that the system of elite education institutions in France did exhibit the same structure as the French field of power.

Controversies

Reoccurring debates on the early works by Bourdieu and his collaborators have addressed the question of to what extent the findings were exclusively French. Even if the concepts and methods have proven to be useful in studies of other societies and other time periods, it would be unwise to assume that the same *results* apply. In most other contexts, for example, the content of cultural capital will probably be different—maybe less marked by highbrow culture, as has often been suggested.

A limitation in the early analyses of the different species of capital and the fields is that the national borders were taken for granted. Therefore, intense efforts have been made to widen the framework to include transnational and global phenomena.

Cardinal Principles of Secondary Education

The *Cardinal Principles of Secondary Education* is a 32-page report issued in 1918 by the Commission on the Reorganization of Secondary Education. The National Education Association formed the commission, chaired by Clarence D. Kingsley, amid concerns about demographic changes from immigration, urbanization, and industrialization, which resulted in a rapid increase in high school enrollment. The commission's 28 members represented a range of education professionals. Serving as members at large, for example, were the sitting U.S. commissioner of education, three education professors, a philosopher, the education secretary of the YMCA, the principal of the Chicago Normal School, a university president, a high school principal, and a state high school supervisor. Their work was intended to guide the education of youth during a watershed period in American history. This entry describes the report, its content, and conflicting interpretations of its influence.

The *Cardinal Principles* report is most widely known for organizing the purposes of secondary education around seven broadly defined objectives. These objectives include the following:

1. *Health*, including instruction in health habits, physical activities, and community health interests

2. *Command of fundamental processes*, particularly advanced language and mathematics proficiencies
3. *Worthy home membership*, with a focus on contributions to wholesome family relations as well as family enjoyment of literature, art, and music
4. *Vocation* education to equip individuals with a livelihood that benefits themselves, their families, and society
5. *Civic education* to develop the qualities, habits, and practical knowledge necessary for individuals to function as members of neighborhoods, towns, states, and nations, and necessary to understanding international problems
6. *Worthy use of leisure* to prepare students in culture and the arts for recreation of the body, mind, and spirit, and for personal enrichment
7. *Ethical character* education and modeling of moral codes that promote personal responsibility in the service of democratic life

The *Cardinal Principles* report remains widely studied for at least three reasons: (1) its objectives as a statement of evolving aims for secondary education, (2) the report's democratic focus, and (3) its contributions toward an enduring model for high schools.

The first reason for continuing interest in the *Cardinal Principles* is that it represents a classic statement of what is called "aims talk" in education. Aims talk is associated with philosophical traditions stretching back to Plato's *Republic* and his "myth of the metals." In this allegory, Plato begins by identifying the needs of Athenian society for three distinct classes: rulers, guardians, and artisans. Although education was to serve social needs, Plato also argued that if young Athenians are carefully selected for gold, silver, or bronze training, the individuals would be personally committed and content with fulfilling their social roles. The *Cardinal Principles* report is often credited with helping to bring this tradition of aims talk into the industrial age. Some have argued that aims talk has waned in recent years. Nevertheless, such periods of neglect have punctuated educational history, only to have aims talk rebound as social and technological changes once again push questions of purpose to the forefront of educational concerns.

A second reason for the report's significance is its explicit emphasis on the needs of popular democracy. Here, the *Cardinal Principles* report is often compared with that of the Committee of Ten, a commission also founded by the National Education Association but 25 years prior to the *Cardinal Principles*. The Committee of Ten commission, chaired by Harvard University President Charles W. Eliot, is generally viewed as confirming the value of traditional academic subjects.

The intervening shift by 1918 to a more progressive stance is often attributed to demographic trends. Prior to the 20th century, high schools were attended by very few adolescents and almost exclusively by those with an elite and affluent social standing. Yet school-age populations were beginning to change by the turn of the century. Enrollments increased, and as a result, schools found themselves dealing with a greater diversity of adolescents with a greater range of interests. Moreover, immigration to urban, industrialized areas was also on the rise, together with a perceived need to assimilate those new to American culture.

Today, the intentions and outcomes of this "democratic experiment" are contested. Some educational historians, particularly after 1960, came to view the *Cardinal Principles* as promoting a rapid proliferation of new high school courses that undermined the report's espoused aims of equity. Other historians have interpreted the expansion of course offerings as an attempt to balance the needs of both psychological and social development. On this point, the report speaks directly to the unique worth of individuals and their right to self-determination. It also stresses the importance of relevant and practical knowledge within the scope of its seven objectives.

A third, and related, reason for continued interest in the *Cardinal Principles* report is that it presaged what many regard as a uniquely American invention: that is, the comprehensive high school. Here, the *Cardinal Principles* signaled a turning point away from the elite and often esoteric curriculum of the 19th century. The report authors do not relinquish the aims of college preparation, but their objectives go well beyond academics to include, for example, home membership, leisure, and calls for vocational programs. From its progressive beginnings, the comprehensive high school was soon to become a cornerstone in the nation's "melting pot," and in doing so, this model for secondary education now continues into the 21st century with only minor changes.

Case Studies

Case studies feature prominently in the educational research literature, but what precisely is a case? It is an in-depth, multifaceted examination of something, where the something can be a person, a group, a class or a school, an organization, a community, or even a process (an instructional episode, an election, a policy being formulated). Sometimes, the issue or phenomenon or problem that is the focus or theme of the case is known before the research work begins, but it is also quite common for the precise nature of the study to emerge during actual work on-site.

A case study can be narrowly focused, or it may cast its net widely and include as part of its examination the complex interactions between many facets of the setting in which the research is grounded. Whatever the research question is and whatever the physical setting, the case study is an attempt to paint a complete picture of the pertinent factors and processes, how they interact, and how these might vary as conditions or circumstances change.

It is important to stress that researchers doing a case study are not attempting a major intervention in the situation, setting, or process that is its focus; they are not attempting to implement a treatment or program (e.g., they are not attempting to ascertain, using a randomized experimental design or a quasi-experimental design, whether Treatment X causes Effect Y)—unless, of course, the process of implementation of a treatment or reform is itself the focus of the case. The purpose of a case study, in short, is to understand what is going on in the situation, or with respect to the problem, that is being studied, why this is happening, and how the various aspects of the case relate to each other.

A detailed example will be helpful here. Consider a researcher who is interested in the phenomenon of homophobia in school sports; she might decide to undertake a case study of a particular high school football team, in a specific school, with the aim of achieving an "ecologically valid," deep understanding of the phenomenon—perhaps for its own sake or before carrying out more focused work involving interventions. Clearly, this researcher's first task will be to select the site in which the case will be developed, for not all sites (not all football teams) will be suitable venues for studying the issue that is the focus (the case here being one of "homophobia in school sports"). Thus, the particular team could be selected because it has a coach who is known to discuss equity in all its various forms, or it is a team in a school that has a past history of homophobic acts, or the school district has active policies about equity, or, as happens in many instances, in this site there is a combination of advantageous factors, including accessibility for the researcher.

While working on the case, the researcher might examine district, school, and athletic department policies; the perspectives and backgrounds of the coaches; students' views of their own and fellow students' and coaches' views of homophobic behavior; the school administration's position and monitoring of related issues; and even attitudes toward homosexuality in the broader community that is the context in which the school—and its football team—operates. She also would go further and examine the interactions among coaches and players during practice sessions and games. As a result of her observations, the researcher might be led to examine the impact of homophobic language on gay and straight players and on team cohesiveness and team climate.

As can be seen from this example, case study researchers use a variety of evidence and attempt to approach the central focus of the case from multiple levels and angles. What might not be as apparent is that data collection is only one aspect of the case study. The analysis, and the depth to which it is conducted, is equally important. Merely to report the data that were collected is to remain at the level of description, and powerful case studies go beyond this.

An important methodological feature of most case studies is that the analysis of data is not relegated to the final stages of work but takes place

throughout the course of the study and actually progressively influences the direction the study takes—researchers examine the data and ask "why" the case functions as it does. In the football team example, if homophobic language is used, why is it used? Is it because of the traditions of the sport and the backgrounds of the coaches? Are some coaches uncomfortable with its use but are having concerns about expressing this? What is the impact on the athletes, both gay and straight? How do district policy and administrators' perceptions and explicit and nonexplicit statements relate to how coaches see homophobic language and behavior?

In other words, the progressive analysis of the data in hand raises further questions—the pursuit of which drives understanding of the issues in the case deeper; and ultimately, the reader of the research can be given an in-depth perspective on what occurred, how it occurred, and why it occurred.

Another point needs to be made about the methodology of case studies. Often researchers, and consumers of research, think that case studies exclusively employ qualitative methods. But this is not an accurate perception, for a case study may use qualitative, quantitative, or mixed methods to collect data. To continue with the football team example, the researcher could use only qualitative methods by taking field notes while observing practices, coach and team meetings, and informal interactions while moving from the locker room to the practice field, on the team bus to a game, and during a game. She also may interview coaches, athletes, other students and administrators, as well as fans of the team. In addition, the researcher may collect materials (e.g., district and school policy manuals, fliers that are handed out to students); she could even go further and photograph locker room graffiti and material on bulletin boards throughout the school. All of this material would provide useful information about the case.

However, quantitative methods might also be used in this study. For example, the researcher might use surveys to document homophobic attitudes for each of the players and for the coaches; she might use data from school district and police reports that describe the number and type of homophobic incidents at the school; furthermore, she might use a systematic observation instrument to observe both equitable and homophobic behavior during practices. The qualitative and quantitative data would complement each other and be used during analysis to get more insight into the case.

Case studies can also be exclusively quantitative. For example, a case study of budgeting practices in an urban school district could use multiyear budgets to examine trends and relationships with a number of factors, including student achievement, teacher hiring and retention, and high school graduation rates. An analysis could be conducted of school board and committee meeting minutes to determine their specific focus on budget issues and the time spent on those issues. Surveys could be conducted of parents, teachers, and administrators about the impact of budget decisions. And economic trends could be analyzed to view the district's budget in context. The analysis would use all these types of data to elucidate what occurred and the relationships between the different types of data.

The main limitation or drawback of case studies is related to their greatest strength. Because they focus on gaining an in-depth understanding of a specific problem, issue, or phenomenon in a specific setting, their findings are not generalizable to other settings. The case study informs us about the unit being studied—about, for example, homophobia in *this* team, with *these* students having *these* backgrounds, with *this* coach, and in *this* school and community. It certainly can provide information to inform other research and to serve as background or a starting point for an examination of what is occurring in other, similar settings.

A reader of a particular case study may find the results and analysis helpful in throwing light on his or her own situation, but how helpful it is will ultimately depend on how many points of similarity exist between the situation of the reader and the setting in which the case study was conducted. Nevertheless, while generalizability is not technically possible, readers often get information from case studies that, if used cautiously, can enhance both future research and professional practice.

Castoriadis, Cornelius

Cornelius Castoriadis (1922–1997) was a Greek philosopher, psychoanalyst, social theorist, and political activist who lived in France most of his life. For a long time, he was best known for his political writings in the group Socialisme ou Barbarie (Socialism or Barbarism), which he founded together with Claude Lefort, but his philosophical work is increasingly being introduced to a range of academic disciplines, such as education. His intellectual inspiration ranges from Karl Marx, Sigmund Freud, and Max Weber to German idealism and the phenomenology of Maurice Merleau-Ponty; but arguably most important was his lasting interest in Aristotle and the ancient Greeks. A key to the increasing interest in Castoriadis is his unique combination of political seriousness and scholarly sophistication, as reflected in his many-faceted, almost encyclopedic work.

Castoriadis saw himself as part of the grand Western tradition, where education and philosophy are two sides of the same coin. He did not write specific texts on education but emphasized its significance in numerous political and social writings, especially those discussing politics and democracy. A central concept in these discussions is the notion of "individual and collective autonomy," which signifies the awareness that societies are self-created and can therefore be re-created in conscious and explicit ways. Democracy, in its original Greek sense, is seen as a regime that facilitates such political creation. However, for democracy to realize its potential as a regime of autonomy, a specific kind of education is required, an education through which the citizens come to see society (or the polis) as their own responsibility.

In ancient Athens—Castoriadis's preferred case for discussing autonomy—the city and the citizens were in fact one and the same phenomenon as covered by the term *athenai*. To become a responsible citizen in this emphatic sense means, for Castoriadis, to become a *subject*. Compared with the social *individual*, who is simply a product of society, a "subject" is a reflexive agent capable of questioning both the world and himself. Thus, while a democratic subject maintains a responsible attitude, he or she does not necessarily accept and defend society as it is—more important for Castoriadis is the capacity to question existing institutions and their grounds, their legitimacy and justification. The great invention of the Greeks was, precisely, to realize that the laws had no other foundation than the commitment of citizens to the pursuit of justice, the quest for truth, and the care for beauty. In the historical case of Athens, philosophy and politics co-emerged in the first manifestation of what he calls the project of autonomy, but this impulse is still more or less active today in modern Western societies.

Citizens in a democracy engage in the political recreation of society's institutions; but autonomy also implies a realization that the world *in itself* is chaos, meaningless, and that there are no extrasocial foundations for the socially instituted world. Autonomy is a project with no guarantees—with the exception of the limits we set for ourselves. This leads us to another, central concept in the work of Castoriadis—the "imagination," which signifies the (human) capacity to create meaning and significations. According to Castoriadis, the social world is instituted by and through significations that have no foundations outside of themselves; that is, they are self-founding and "imaginary" in a "radical" sense—they are the instituted meanings that hold a society together and are embodied in its institutions. Like autonomy, the imagination has a social and an individual side (the terms he uses are the social historical and the psyche). In his main oeuvre, *The Imaginary Institution of Society* (from 1975), Castoriadis discusses the creative role of the imagination in various regions of thought, such as historiography, ontology, psychoanalysis, the philosophies of time and language, and social theory. Large sections are devoted to the development of the notion of social imaginary significations related to an ontology of the social historical, thus forming a comprehensive alternative to methodological individualism and functionalist thought.

The Imaginary Institution of Society was not translated into English until 1987, and it remains his only monograph. His other publications consist of various collections of essays and talks, some still awaiting translation into English. The most important collections in English are (in chronological order) *Crossroads in the Labyrinth* (1984), *Power, Politics and Autonomy* (1991), *World in Fragments* (1997), and *The Castoriadis Reader* (1997). His seminars on Greek history and thought, *Ce qui fait la Grèce* (2004, 2008, 2011; Volumes 1–3), are also seen as central.

In some of these essays, Castoriadis elaborates the connection between education, subjectivity, politics, and psychoanalysis. As a rule, however, his conceptual discussions were an integral part of broader discussions related to political and moral problems. In the latter part of his life, two such problems emerged that made him concerned about the future of politics, in the emphatic meaning of the term, namely, the impending climate crisis and the inability of contemporary institutions to facilitate political creation. In this situation, education becomes more important than ever, yet its direction remains unclear and the grounds for hope, uncertain.

Castoriadis's work is the subject of growing international interest, and numerous publications are currently emerging in political theory, philosophy, classical history, civilization theory, mathematics, social theory, and many other disciplines. An original and demanding thinker, Castoriadis seems to appeal to students especially. One plausible reason for this is the urgency with which he addresses the themes of his time, such as the ecological crisis and the crises of creation and politics, as he saw them.

Causation

Causation is an everyday notion that we often employ unblinkingly to navigate the contingencies of our lives. We take it for granted that putting your hand in boiling water will cause your skin to blister, alcohol on a scratch will cause the sensation of burning pain, and pressing the brake pedal will cause the car to stop. We also more or less accept that smoking can cause lung cancer, that wanting to return a book can cause a student to walk into the library, and that inadequate preparation will likely cause low exam performance. But does "cause" have the same meaning in all of these cases? The temporal and logical relationships between these events, as well as the nature of the events themselves and their practical implications, seem to vary. Is there anything they have in common? Can their web of resemblances be traced?

This entry introduces some of the ways in which philosophers have attempted to answer these questions. It highlights the ontological and epistemological complexities of the notion of causation and connects them to debates in social and educational research. Finally, it notes the debates around the merits and limitations of causally oriented projects of educational research.

Defining Causation

There are many contexts for everyday and specialized uses of the terms *causation* and *causality*, and of their relations, including not only cause, effect, event, condition, phenomenon, process, and variable but also law, rule, regularities, correlation, probability, as well as determination, explanation, and prediction. Further complexity comes from the diverse metaphysical perspectives on causation, ranging from seeing it as a fundamental feature of the world, to seeing it as reducible to noncausal facts, and even to not seeing it as a feature of the world at all but a category through which we understand it. This diversity has implications for the epistemology of causation, for example, in describing the sources of causal beliefs as direct perception or as inference from experience, or in viewing them as a priori, and in finding ways in which causal relations may be modeled.

The history of philosophy abounds in examples and counterexamples that show how lastingly complicated the task of defining causation is. For example, Aristotle developed a theory of causality and of explanation that distinguished between four causes, only some of which overlap with current uses of the term and which may coincide in time with the effect: (1) material (e.g., the bronze of a statue, the silver of

a saucer); (2) formal (e.g., the triple meter in defining a waltz); (3) efficient (e.g., the father of a child, the adviser of an action, the maker of an artifact); and (4) final, or teleological (e.g., health as the end, or aim, of exercising).

In contrast, for Hume, causation is based on a habit of the mind arising from repeated experience of a regular succession of events, which enables it to establish connections, or associations, between ideas. Causal beliefs are inferred from past experience of customary conjunction between the (antecedent) type of object or event and its regular and contiguous successor. Causal ties, or connections, are not necessarily a priori, nor are they directly observed as such. The sense of necessity accompanying them arises from the experience of constant conjunction; thus, causal statements are tentative predictions that the same succession of events will continue in the future.

Kant responds to Hume by advancing a conception of both causality and necessity as a priori categories of understanding, which are prerequisites for our meaningful experience of the world. Causality is a condition of the possibility of the experience of sequence or succession, and thus of empirical claims about change and stability. The causal principle is thus justified "transcendentally": It is neither purely inductive nor purely deductive and neither purely empirical nor purely rationalistic but what Kant calls a synthetic a priori proposition, which is at the same time substantive and independent of empirical experience.

Theories of Causation

Traditional accounts of causation, such as those noted above, are still the kernel of current debates, including those between pluralist/generic and singular/particularist accounts of causes and effects; fundamentalist and reductivist, or (physical) realist and (mental) attributionist ontologies of causation; deterministic and probabilistic views of causal relations; and analyses of actual and potential causality. Building on and sometimes challenging these accounts, philosophers have refined this conceptual palette to explicate causation in ways that speak to current scientific and technological developments. In these refined accounts, regularity, antecedence, and contiguity still feature heavily; sufficiency and conditionality have also maintained their grip; probability and counterfactuality have taken leaps; agency and process have made intriguing comebacks. There are profound disagreements about the definition of each of these concepts, about their sometimes conflicted relationships with each other, and about their articulation with the wider notion of causation. What follows is the briefest whistle-stop tour of some of these theoretical proposals; Beebee, Hitchcock, and Menzies's edited collection, which includes chapters on each of these theories, is a good starting point for further exploration. Some of the best-known recent theories of causation attempt to account for it in terms of the following.

Regularity

A wide-ranging group of contemporary theories of causation, influenced by Hume, hold that causation is based on mind-independent regularities rather than on natural powers of necessity (as a metaphysically thicker conception of causality might suggest, such as Harré's ontology of real "causal powers").

Minimal Sufficiency

In tight connection with the regularities account, empiricists such as Mill have argued not only that causes are not fundamental "forces" in the world but also that they are "antecedents" that jointly (and also in the absence of negative contingencies) form a sufficient condition for an effect. Whenever this condition is realized, it will be invariably followed by the same type of consequent. The relationship thus depends on generic regularities, or "covering laws." The notion of covering laws inspired Hempel to develop an influential account of causal explanation, the so-called deductive-nomological model. In this account, a causal explanation consists of a deductive argument from a set of relevant antecedent conditions and lawlike statements to the occurrence of an event. Identifying and describing both antecedents and laws is far from straightforward, however. Mackie proposed an account, occasionally cited by social scientists, that allows for complex regularities and plurality of causes. He describes causation in terms of combinations of factors that are minimally sufficient for bringing about an event but that may not be necessary (as other combinations may also be sufficient). Each factor in these combinations is a "cause" in the sense that it is an "INUS" factor, or an insufficient but nonredundant part of an unnecessary but sufficient condition made up by each of these clusters of factors. For the social sciences, this account faces the difficulty of distinguishing, among the different factors, between a cause and a merely spurious contingency.

Counterfactual Dependence

Counterfactual analyses of causation introduce a notion of possibility to test the relationship between cause and effect as distinct possible events: In Lewis's definition, E causally depends on C because if C were the case, then E would be the case, and if C hadn't occurred, E would not have occurred either (counterfactual). Counterfactual dependence can be deterministic or probabilistic (in the latter case, E would have had a different probability of occurring). Such accounts of causation have been attractive to evaluation researchers, as well as to quasi-experimental research; however, these areas of research have also raised challenges to counterfactual approaches, such as the need to accommodate common and competing causes and alternative causal chains, or the difficulties in accounting for negative causation and for overdetermination of social events.

Probability

Even more attractive for many social researchers has been the account of causation in terms of the probability of effects. In a simple theory, causes increase the (calculable) probability of effects. Thus, as argued by Salmon, sufficient causes become a "limiting case" of probabilistic ones. The logical empiricists of the 1920s and 1930s grappled with mathematical notions of probability, but it is in more recent decades that the design and application (e.g., in artificial intelligence) of mathematical techniques for calculating probabilities and modeling causal relationships (e.g., Bayesian causal nets) fully took off. Showing probabilistic dependency does not, however, always amount to a full causal explanation. Some dependencies can be accidental; social and educational research is full of correlations that cannot be interpreted causally, although they may indicate probabilistic dependency. Sea levels and higher education enrollment may have grown over the past century, but if they happen to be correlated, the correlation would be of little help in constructing a causal explanation of either of the two.

Process

Descriptions of causation in terms of relations between discrete contiguous events can quickly run into problems—not the least with regard to carving space and time into sequences of sufficiently narrow or wide causes and effects. Salmon and others proposed to address this issue by focusing instead on the interactions between continuous processes. This proposal may accommodate some important features of, in particular, physical causation; however, for the social scientist, questions of negative causation, historical causation, or mental causation continue to loom large.

Intervention

Manipulation of variables is key to (human) agency- and (human or nonhuman) intervention-based approaches to causation. The basic idea that manipulating a variable (cause) may lead to a change in the value of another (effect) underpins experimental and quasi-experimental research. Early agency-based theories of causation were criticized for their anthropocentrism, but as noted by Woodward, more recent versions of intervention theories have been refined to allow for nonhuman intervention, for combinations of interventions, as well as for multiple and contributing causes.

This conceptual diversity, together with its unresolved tensions, is echoed in the ways in which education and other social researchers state their aims, frame their inquiries, and stake their claims.

Challenges for Education Research

Questions about the nature of causation might not always occur to us in the relentless flow of everyday life, but they matter deeply when people attempt to build descriptions and explanations, draw inferences, and make predictions. Research, including social and educational research, is a systematic way of attempting these tasks, and thus it grapples with issues of causation at all its stages—including asking research questions, analyzing research data, interpreting research results, and critically assessing competing claims from research. For example, Morrison discusses 10 possible ways of framing and answering the question "Why do East Asian students perform better than their Western counterparts in international studies of educational achievement despite discredited pedagogical practices of rote memorization and drill?" Rival explanations of the differential in performance have been developed within particular bodies of literature, which have operationalized the question in their own ways and some of which have produced causal claims seen as contestable by other traditions. Further testing of these tentative explanations and working out of their implications for action may be limited by practical and ethical considerations, which often make it more

feasible to plan for a correlation study (yielding a set of stronger or weaker regularities that may or may not be accepted as evidence of causal relations) than for a study attempting manipulation of causal variables, which would try more directly to focus on the relationship between purported causes and effects. Recent pressures on educational research to demonstrate "what works," for whom, and in what circumstances have led to more emphasis on experimental designs, and in particular on randomized controlled trials, which test the effectiveness and efficacy of an intervention by comparing treatment and control groups of randomly allocated participants.

Despite this interest, there is extensive debate about the grounds for causal claims in the social sciences, including educational research. Three decades ago, Lincoln and Guba went so far as proclaiming causality a "placeholder" theory akin to those about ether and phlogiston, and equally useless in research. Common objections to the possibility of causal explanations in the social sciences refer to difficulties in testing causal claims; it is argued that, as perfect isolation of social phenomena or variables is not possible, the ceteris paribus (other things being equal) condition for claiming causality from experimental manipulation cannot be achieved. It is argued that this limitation, coupled with difficulties in establishing causal chains among phenomena that are aggregate in character, undermines the epistemic status of causal generalizations in the social sciences. Probabilistic explanations seem more common in the social sciences than deterministic ones, and even in the case of the latter, the apparent causal overdetermination of any social event makes causal claims laborious to produce and complicated to define and qualify. There are also limits to the capability of statistical techniques to model causal relations and to distinguish them from, for example, relations of supervenience or covariance—which may show that relationships exist, without explaining why.

In addition, both the phenomena researched and the tools and perspective of the researcher are infused with various social meanings; as a result, some social scientists have stated the aims of their inquiry in terms of understanding, or *verstehen*, and critique and have distanced them explicitly from (causally) explanatory aims. In so doing, they may reject arguments, such as Davidson's, that reasons (as combinations of attitudes and beliefs) are causes for action, and thus that explanations in terms of reasons are a subspecies of causal explanation; instead, they may argue that illuminating and interpreting human action, if at all directed at explaining it, would lead to descriptive or teleological, rather than causal, explanations.

Furthermore, critiques are framed in terms of the dynamics of scientific development: While deterministic and nomothetic conceptions of science may make intervention research and the testing of causal hypotheses the "gold standard" or pinnacle of good research, naturalist and poststructuralist conceptions of science are suffused with heightened awareness of the relations of power and control that may underpin public and political interest in research leading to causal explanations and predictions.

Cavell, Stanley

The contribution of Stanley Cavell (1926–) to thinking about education is not to be found in any curriculum reform, or in the promotion of any philosophical position, or in the delineation of any theory. Hence, it is not surprising if his name is less familiar among educationalists than that of, say, John Dewey, Jean-François Lyotard, or Michel Foucault. Yet it would be no exaggeration to say that education is Cavell's abiding theme. Hilary Putnam has called Cavell one of the most creative thinkers today and "the only living American transcendentalist" (conversation with Putnam, March 2012). Indeed, Cavell takes up themes that are there in Ralph Waldo Emerson and Henry David Thoreau—centering on the idea of moral perfectionism—as well as building on insights into teaching and learning that pervade the writings of Wittgenstein (these three, in addition to J. L. Austin, being the most powerful influences on his work). Extending the boundary of traditional philosophy to literature, art, and film and opera studies, he returns philosophy to the world of the ordinary.

A philosophical entry point into his work is provided by the topic of skepticism. Epistemologists since the time of René Descartes have addressed the questions of how there can be knowledge of an external world or knowledge of other minds, and it has widely been taken that Wittgenstein's *Philosophical Investigations* provides a refutation of such doubt. It is not that Cavell wishes exactly to deny this, but he does take the view that this is to miss the book's point. That point is rather to express the existential truth in skepticism: Skepticism in epistemology is to be seen, then, as a manifestation within philosophy of a more general disturbance in human life—the human tendency to call into question its own condition (Cavell, 1969, 1979). The philosopher's skepticism needs to be seen, on this account, as related to the kind of doubt that bedevils a Shakespearean hero, such as Othello (How can he know that Desdemona has not been unfaithful?) or Leontes in *The Winter's Tale* (How can I know that this is my son?) (Cavell, 1987, 1988). It is a short step from here to the multiple ways in which we doubt, to our cost, what we ordinarily know—as, for example, where the experienced teacher's folk psychological knowledge is disparaged in favor of expert opinions or where, in the absence of the testing of behavioral outcomes, learning is assumed not to have taken place.

This Wittgensteinian suspicion of theory's tendency to part company with the rough ground of reality is evident also in Cavell's repeated turn to the ordinary conditions of human life. In *The Senses of Walden* (1972), he shows how Thoreau's "economy of living" serves to challenge prevailing conceptions of accountability—including the ways we account for ourselves, which is to say, both the way we justify the way we live and also the kinds of narratives through which we conceive of ourselves. Cavell shows how Emerson's preoccupation with the common calls into question what it is that human beings in fact have in common, revealing this not in terms of some set of developmental characteristics but rather in terms of a virtuous aspiration: the aspiration to find common ground with others while acknowledging the uncommon. This is perfectionist, not in the fantasy that a perfect world is realizable but insofar as the human being is, as it were, always charged with the responsibility to improve the hour (in Emerson's phrase). This should prompt us to not only react with shame at what is wrong with our societies and our lives but also address this with hope and action committed to a better future.

Sometimes, Cavell's text is perceived to be overly preoccupied with language, even to be engaged in so-called linguisticism, but in fact, his philosophical commitments regarding language have essential social and political implications. Cavell (1984) says that the transcendentalism of Emerson and Thoreau underwrites ordinary language philosophy. He rejects the common understanding of Emerson and Thoreau as belonging to the American *literary* heritage—on the grounds that this silences their philosophical import. They are, like Dewey, committed to "democracy as a way of life."

Like Dewey, and Emerson and Thoreau before him, it certainly makes sense to see Cavell as a distinctively *American* philosopher. For him, as for them, the idea of America, its original promise and its betrayal of that promise, is never far away. But this is by no means to conceive of America in exclusive terms or to see it as a fixed identity: America

understood in perfectionist terms is still to be discovered. This is a thought always open to intercultural horizons.

Cavell's antifoundationalist, Emersonian perfectionism contrasts with Dewey's pragmatism in its greater sense of the provisionality and precariousness of the steps we take. Beyond anything offered in the exchange of communication, language itself trembles. Even a brief encounter with the texts of Dewey and Emerson already reveals a stylistic difference: Dewey's steady, sometimes monotone, homeostatic prose (encouraging balance between two extremes) contrasts with Emerson's capacity to wrong-foot the reader, arousing her from any merely passive absorption of the text, compelling her to think, and compelling her to *read*; this, in Thoreau's (1854/1992) phrase, is "reading in a high sense." Cavell is Emerson's equal in this respect. And here, in reading itself, there is a signal lesson for education, regarding the effects of the texts that are presented to students and what they are expected to gain from them. There is a lesson concerning what education can be. Thoreau subverts the idea of the "common school," which might figure as offering a kind of consolidated socialization, by claiming that what we need is rather the "uncommon school," a place to encounter strangeness in the common, the familiar. Our education will, otherwise, be "sadly neglected" (Thoreau, 1854/1992).

The subtitle of Cavell's *Cities of Words: Pedagogical Letters on a Register of the Moral Life* (2004) effectively expresses the educational intentions of so much of his work, and the book has innovative intercalation of the chapters on great philosophers with the chapters on great films. This reaffirms Cavell's (1881, 1996) faith in the educational value of cinema. Indeed, it is to the films that he saw as he was growing up that he attributes a major part of his own education. These are typically Hollywood "talkies," which means, of course, that they foreground conversation. Their central character, usually a woman, is trying to find her own voice, retrieving it from its suppression, typically by a man. The themes and tone of Emersonian moral perfectionism are worked out in Cavell's depiction of the endless perfecting of the central characters and the other through mutual education. Education is seen to be inseparable from the finding of one's voice. Yet this is something other than what one finds in contemporary affirmations of "student voice." Drawing its significance from the recognition within philosophy of the particular importance of first-person utterance (in Soren Kierkegaard, Ludwig Wittgenstein, and, crucially, ordinary-language philosophy), and from the sense that I must stand behind or be present in my words, the nature of the emphasis on voice is exemplified in *A Pitch of Philosophy: Autobiographical Exercises* (1994) and the substantial memoir, *Little Did I Know* (2010). Indeed, reclaiming the voice in philosophy, against its systematic suppression by the foregrounding of impersonal third-person utterance, is one of his central tasks in philosophy, and this provides the impetus to the adoption of the motif of philosophy as autobiography. Philosophy understood this way is less a set of problems to be solved once and for all than an obligation to be addressed continually, day by day. Without this, our words go dead on us, and the responsibility we bear for this is not only personal but also political.

This begins to reveal the ways in which Cavell's sense of the common and the communal cuts across familiar dichotomies of liberalism and communitarianism. The impulse here is something other than a political developmentalism or politics of recognition, expressed as "mutual respect," "understanding via communication," or "learning from difference." Cavell (1990) says that there is no society before individuation; and self-reliance and the orientation toward the other coexist as a paradox, the very condition of human being. Cavell is drawn recurrently to a vocabulary of sin and redemption. This is not likely to be understood within familiar ideals of autonomy or care ethics. For similar reasons, it is important to emphasize that his work disrupts dichotomies of subject and object, or inner and outer, the hardening of which causes so much confusion in research in education.

Emersonian perfectionism too is there in conversation with others, perhaps with the friend who does not passively nod in agreement or bring consolation but who confronts us with our own shame (i.e., the degraded state of our democracy), challenging us continually to the next, best possibility of ourselves. Conversation with "this another of myself" is crucial to the recovery of political emotion, the release from cynicism. Can we expose ourselves to this ongoing education? This is why philosophy, as Cavell conceives it, is in the end no less than the "education of grown-ups" (see Saito & Standish, 2012).

Century of the Child, The: Ellen Key

Ellen Key (1849–1926) figures among the few internationally known Swedish educators; but her texts, penned in a spirited and often provocative style, also deal with political issues such as feminism, marriage, religion, and politics. She is best known for her book on education, *Barnets århundrade,* which was translated into English as *The Century of the Child*.

She was educated in the family mansion itself, being submitted to a rigid educational atmosphere. Her mother, an aristocrat, taught her mathematics and grammar, while her nursemaids taught her foreign languages. When her father, the founder of the Swedish Agrarian Party, was elected to Parliament, the family moved to Stockholm. Here, Ellen Key finished her education in a private school, but she acquired a great deal of knowledge as an autodidact. From 1874 onward, she regularly published articles in several newspapers, before beginning to work as a teacher in 1880, most notably at the Worker's Institute of Stockholm. After 1903, she made a living by publishing her texts.

Inspired by various of her acquaintances who had a political, feminist, or scientific background, Key soon broke with the ideas of her milieu: She abandoned liberalism for socialism and abdicated the Christian faith to embrace a scientifically oriented moral system inspired by Charles Darwin and Herbert Spencer. A constant tension is clearly perceivable in her texts: How can the liberty of individuals be reconciled with the welfare of the community? What kind of society needs to be promoted in order to ensure women's equality while at the same time providing the best conditions possible to enable them to fulfill their roles as mothers and educators?

Her writings bear testimony to her remarkable ability to synthesize the intellectual debates of her time in a very personal vision. Hence, the ideas on education, women, and school brought forth in *The Century of the Child* are not completely new—the

originality, for example, consists in how she balances her appeal in favor of children with the fight against the degeneration of the human race.

The first chapter of the book invites its readers to abandon the "Christian concept of life," with its vision of a fallen human nature and its contempt for sexuality. Key calls for the suppression of religious instruction, which she judges to be antiscientific, hostile to individual progress, and abetting hypocrisy. Instead, she adopts a scientifically oriented morality and worldview that make her more optimistic of improving humanity. Rejecting authoritarian state measures (e.g., compulsive sterilization or prohibition of marriage), she asks for a positive eugenics that incorporates a sense of responsibility regarding sex and procreation, and she has confidence in the possibilities of producing a superior type of human by improving living conditions and reforming education. According to Key, the "future race" would not only be more capable but also happier. For a child's optimal development, the parents' reciprocal love matters as much as the child's own health. Thus, the search for individual happiness is reconciled with the future common welfare.

Her eugenic vision leads her to argue in favor of more differentiated gender roles. The women's primary task lay with the children's care and education, thereby making it unacceptable for women to work in factories as this would lead to child neglect and degeneration. The author draws a sinister picture of the social and sanitary consequences of woman-and-child industrial labor. She accuses feminists, with their strong focus on the economic independence of women, of egoism; the limits of female liberty are set by the potential development of every child. Being in favor of protective labor laws, in her later texts, she demands stronger support for mothers via a maternal salary.

Key, in her educational advice, absorbs ideas from Jean-Jacques Rousseau, Johann Wolfgang von Goethe, and Herbert Spencer. According to Key, the tasks of educators include accompanying children during their experiences, caring for their environment, refraining from constantly correcting them, and promoting their individuality instead of imposing stereotypes. From her evolutionist point of view, individual variability proves crucial to the "progress of the race." An educator must stimulate the child's will to leave the beaten track, provided it does not violate the rights of others. It is important to create an atmosphere of harmony and respect within the family, where parents are partners, brothers and sisters are treated as equals, and children participate from an early age in household chores. Key vehemently opposed castigation, something she associated with a lower degree of civilization; beatings signal the parent's lack of intelligence and patience and aggravate the child's hatred and anguish, while hurting his or her dignity and sense of justice and thus leading to later brutal behavior. Intelligent punishment consists in inviting children to control themselves in the face of the fundamental rules of social life. Therefore, it is a lot more effective to explain to crying children that their crying is unbearable to others than to cane them.

Key ranked among the contemporary critics of the school system, pointing to brainwashing, passive pupils, overloaded schedules—so much inadequateness killing off any appetite to learn, any gift of observation, reflection, or imagination. Key's book concludes with a utopian vision of tomorrow's school. She opposes nursery schools (kindergarten), which "free children from their natural individual obligations and put in their place demands that can only be fulfilled *en* masse" (Key, 1909, p. 244); on the contrary, the home should allow children to learn to be free, to provide mutual help, and also teach them the authenticity of human relations. Only at the age of nine should the child attend a completely reconditioned school where there would be individual teaching and free choice of subjects and activities. At the age of 15, specialized schools would prepare students for specific activities, thus encouraging diversity in talent and individuality.

Published in 1900, *Barnets århundrade* was quickly translated into German (1903), French (1908), and English (1909). Her ideas were widely discussed in German-speaking countries and influenced the child study movement in the United States, which emphasized the importance of observing children to intervene appropriately in their education. Her criticism of the school system joins her with the founders of the New School (John Dewey, Adolphe Ferrière, and Ovide Decroly), promoting active methods and an individualistic education. However, Key's rejection of nursery schools had no impact on contemporary educators (Friedrich Froebel and Maria Montessori). Her maternalism firmly opposed Key to the feminism of the American Charlotte Perkins Gilman, who strongly objected to the idea of women specializing in being mothers. But Key joined other feminists, such as the German Hélène Stöcker, in their will to shake off the yoke of bourgeois sexual morality and to financially assist

mothers to ensure their economic independence and social acknowledgment. Her maternalism also earned her a certain disdain in the history of feminism. Recent works by scholars such as Ann Taylor Allen suggest revising this historiography. Key's legacy, like that of other maternalist feminists, consisted in liberating women from the legal yoke and the traditional ethic of sacrifice.

Character Development

Views of character development are shaped to some extent by the view that is held of the nature of human beings. If one considers humans to have a split self, as marked, for example, by the dichotomy between reason and desire or emotion, then character development is viewed as enhancing the capacities of reason to control the wayward passions, as Plato held. Some have the view that punishing unruly emotions and training reasoning with rules and willpower is the route to good character. But these are misleading beliefs; harsh approaches are more likely to mar character than form it. Although it is true that self-control is necessary for the ethical life, well-constructed emotions are actually foundational for adaptive responses. Under normal (optimal) conditions for development, there is no bifurcation in the self. When there is a bifurcation, it is a sign of pathology and impaired sociality, and it is a source of poor social decision making.

Emotions are evolved systems that codevelop with cognition in early life and (in evolutionary terms) increase human adaptation. But emotions must be thoughtfully cultivated, particularly at the beginning of life—humans are dynamic systems whose early beginnings have great import for later functioning, including ethical functioning. From the beginning of life, the child is ready for reciprocal companionship with the mother and other caregivers. The infant coconstructs a social world in which ideally she is practicing intersubjectivity and synchronous interaction and learning how to communicate emotions and thoughts in truthful ways and how to repair communication when it breaks down. These experiences build brain systems that underlie attachment and social skills, both of which facilitate ethical functioning later. A well-built human being has brain functions that have been shaped well by early experience, when the brain is most malleable and establishes homeostasis and thresholds for most body–brain systems.

We know much more from developmental science about the impact of early experience on character development (e.g., how cooperative, agreeable, and conscientious one is). As Kochanska (2002) has noted, warm, mutually responsive caregiving facilitates the development of attachment, self-regulation, empathy, and conscience in childhood, predicting prosocial behavior. But what other early experiences facilitate ethical character development?

Intensive parenting practices existed among the social animals that emerged more than 30 million years ago. Human evolution intensified parenting further, due to the relatively great immaturity of the human newborn. The evolved developmental niche (EDN) was a matchup between early caregiving practices and the maturational schedule of the needy infant (born at full-term with the brain at only 25% of an adult brain); parenting practices include things such as extensive breast-feeding, nearly constant touch, free play, social support, verbal interaction, and responsiveness to the cues of the child. Parenting that includes caregiving that matches up with infant

development encourages the development of healthy systems (e.g., genes that control anxiety are turned on; stress response systems work properly and do not become hyperactive; the vagus nerve, which underlies multiple physiological systems including social interaction, develops well). Each of the aforementioned practices has been linked to early moral development in young children (e.g., self-regulation, empathy, and conscience).

Moral Development

Early life care that matches the EDN ensures that cognition and emotion are well established and integrated. If this does not occur, the individual may have well-functioning analytical skills but diminished emotional and social capacities; or the individual may display poor thought processes and disordered emotions that mislead in action and decision making, harming self and others. In either case, the result can be a lack of coherence between emotion and cognition and/or deficient practical and ethical wisdom.

It is well known that prior actions narrow current choices. This is especially true in the case of care for young babies, who do not have the autonomy to make their own choices and design their own care and development and are thus at the mercy of the decisions made by their caregivers. Thus, denying babies the EDN can have long-term psycho-bio-social effects that influence subsequent ethical capacities; children who fail to develop secure attachment are more aggressive and less socially skilled, and those who display callousness and a lack of self-regulation are on a trajectory toward antisocial personality in adulthood.

Although some contend that ethical traits can be separated from other traits, or that character traits consistently adhere to a person across diverse situations, empirically it has been found that humans display varying ethical responses according to their degree of experience with a particular type of situation. Typically, the consistency in ethical response adheres to situations in a person-by-context interaction (e.g., Maria is always kind in family situations but cruel in work situations, and for Draco, the pattern is opposite).

Furthermore, although there has been much ado about a genetic cause for antisocial character, at present, there are no known genes that fully determine this. For example, the gene that regulates levels of monoamine oxidase A plays a role in development by altering the levels of serotonin and norepinephrine, decreasing the development of inhibitory control and increasing fear memory, which then leads to increased violence. Many people carry a variant of this gene that is linked to violence, but—crucially—they become violent as adults only if other environmental factors were present in childhood (e.g., abuse, neglect). Thus, experience, especially in early life, may play a codetermining role.

Humans have the potential for self-development throughout life. After childhood, the individual selects experiences and environments that influence how and what virtues develop. What one practices with attention and immersion molds desire and habitual response. To develop a virtuous character, as Aristotle pointed out, one needs extensive practice under the guidance of mentors until one is able to make virtuous choices about activities and friendships. In early life, mentors are one's parents and family. Thereafter, they include teachers and neighbors and opportunities for community involvement where ethical skills are fostered and practiced.

In modern societies, where both parents are working, many opportunities for ethical mentorship arise in schooling experiences. Ethical character is more likely to be fostered by classrooms and schools with particular characteristics including caring relationships between teachers and students, positive supportive climates that convey high expectations, opportunities for guided social skill development, and the practice of ethical action in the larger community.

What capacities needed for ethical behavior can be fostered in school settings? James Rest identified four psychologically driven components of ethical behavior, all of which are required for successful completion of an ethical action. Ethical sensitivity involves capacities for perception, imagination of possibility, and interpretation of ethically relevant events. Ethical judgment involves judging which action is the most ethical in the circumstance based on reasoning skills and code application. Ethical motivation or focus means that the individual prioritizes the ethical action over other interests and goals at the time and, with an ethical identity, does so routinely. Ethical implementation requires knowing what steps to take and persevering through obstacles until the ethical action is completed. There are multiple skills that underlie these processes that students can practice and hone toward expertise. A novice-to-expert pedagogy guided by a mentor (a) immerses students in examples and

opportunities to understand the skill in action, (b) offers chances to practice skills in multiple ways, (c) guides students in practicing real-life problem solving applying the skills, and (d) integrates procedures and skills across multiple contexts.

Character development continues across adulthood, promoted by continued brain maturation. In early adulthood, the prefrontal cortex reaches its pinnacle, enabling greater empathy and foresight, facilitating executive functions that are needed for further self-development. Brains continue to mature into middle age, leading to greater synthesizing capacities, insight, and wisdom.

Adults with a virtuous character exhibit a commitment to ongoing self-development. They use moral imagination to take multiple perspectives and foresee consequences. They coordinate multiple factors in moral deliberation, such as intuitions and principles. They demonstrate habituated moral concern and capacities for moral dialogue about collective interests and the regulation of moral institutions. They also have a sense of responsibility for living a sustainable life that takes into account the natural world and future generations.

Charter Schools

Charter schools in the United States (and some other countries—see below) seek to reform public education through a blend of elements found in public schools (universal access and public funding) and elements often associated with private schools (choice, autonomy, and flexibility). While the definition of charter schools varies somewhat by state, essentially they are nonsectarian public schools of choice that are free from many regulations that apply to traditional public schools. Over the past two decades, charter schools have remained one of the most widely discussed and debated topics when it comes to U.S. school reform. This entry discusses the policy objectives and theoretical arguments for charter schools, research on how they have performed in relation to their objectives, and the challenges and obstacles facing charter schools.

The "charter" agreement establishing each charter school is a performance contract that details, among other things, the school's mission, program, goals, and means of measuring success. Charters are usually granted for three to five years by an authorizer or sponsor (typically state or local school boards). Authorizers hold charter schools accountable for meeting their goals and objectives related to their mission and academic targets. Schools that do not meet their goals and objectives or do not abide by the terms of the contract can have their charter revoked or—when it is time for renewal—not renewed.

The charter school movement has grown rapidly from the first two charter schools opening in Minnesota in 1992 to more than 5,500 schools in 41 states and the District of Columbia as of 2012. Estimates of total student enrollments in 2012 are that close to two million students are enrolled in charter school within the United States; this accounts for nearly 5% of all public school enrollments. While the impact of charter schools appears minimal at the national level, a dozen cities or school districts

have seen the proportion of charter school students rise to capture more than a third of all public school students.

Beyond the United States, charter schools can be found in Canada and Puerto Rico. The charter school concept is also very similar to reforms initiated in other countries at approximately the same time. In the United Kingdom, there was the creation of grant-maintained schools, and in New Zealand and Sweden, independent schools were initiated. These various reforms are part of a larger set of national and international trends that have sought to restructure public education through decentralization, site-based management, privatization, and the use of market mechanisms. Proponents argued that restructuring public education would make it more efficient and responsive. One of the main reasons for the rapid and widespread growth of the charter movement in the 1990s was that it provided a vehicle to pursue many or most of the goals related to school restructuring. Another reason for the growth of charter schools is that this reform has been championed by a wide range of supporters, from those who saw these schools as a stepping stone to vouchers to those who saw charter schools as a compromise that would avoid vouchers and widespread privatization.

Policy Objectives and Theoretical Arguments

Charter school reforms involve a set of policy changes—brought about mostly through changes in state law—that alters the legal, political, and economic environment in which schools operate. The structural changes provide an opportunity for charter schools to experiment. Thus, the charter concept is rather different from other education reforms in that it does not prescribe specific interventions; rather, it was designed to change the governance and conditions under which schools develop and implement educational interventions.

At the heart of the charter concept lies a bargain. Charter schools will receive enhanced autonomy over curriculum, instruction, and operations, but in exchange, they must agree to be held more accountable for results than other public schools. This new system of accountability holds charter schools accountable for outcomes—many of them articulated in the charter contract—and then employs deregulation to allow them to choose their own means for arriving at those goals. If charter schools do not live up to their stated goals, they can have their charter revoked or not renewed when it expires. This type of accountability is referred to as performance accountability. Charter schools also are steered by market accountability since these are schools of choice and money follows the students; therefore, charter schools that fail to attract and retain students will, in theory, go out of business. Yet closure rates are relatively low, and most charter schools that close do so because of financial mismanagement rather than performance or market accountability. The burden of producing evidence regarding charter school success has shifted to external evaluators or authorizers. Charter schools—on the whole—have not been proactive with regard to accountability: Instead of being "evaluating schools" that would take responsibility for evaluation and demonstrating success, they have become "evaluated" schools.

A common policy objective seen in state charter school laws is that charter schools would empower local actors and communities to start their own schools. In the 1990s, local groups and individuals were most often involved in starting new charter schools, but since 2000, the trend has been for outsiders, particularly private education management organizations (EMOs), to initiate the process of opening new charter schools, which are then steered from often distant corporate headquarters.

Another policy objective often found in charter school laws is that these new schools would create new opportunities for school choice. With few exceptions, they are open to students from any district or locale. Theoretical arguments suggest that school choice will lead to sorting by preferences, which will reduce the amount of time schools spend resolving conflicts among school stakeholders, leaving them more time and energy to devote to developing and implementing educational programs. Related to this is the belief that the very act of choice will leave students, parents, and teachers disposed to work harder to support the schools they have chosen.

As commonly articulated in charter school laws, these new schools would have open access to all students. Evidence, however, suggests that charters attract and enroll groups sorted by race, class, ability, and language. In terms of ethnic composition and the proportion of low-income students, three quarters of existing charter schools have student populations that differ from those of local school districts by more than 10 percentage points. In terms of student composition based on students with

disabilities or students classified as English-language learners, the findings show substantially larger differences, with charters serving far fewer of these students than district schools.

A common policy objective for charter schools is that they enhance opportunities for parental involvement. Parents who choose schools can be expected to be more engaged than those who do not. Beyond that, proponents of the charter concept contend that such involvement is a valuable resource that will ultimately lead to higher student achievement and other positive outcomes. The research evidence to date indicates that charter schools have been able to enhance parental involvement. Evidence suggests that parent satisfaction has been one of the strengths of charter schools. Most of this evidence, however, is based on surveys of parents whose children remain in charter schools and excludes parents whose children have left these schools. Nevertheless, the fact that charter schools are growing in size and number is a strong indication of the demand that still exists for these schools.

Another policy objective linked with charter schools is enhanced professional autonomy and opportunities for professional development for teachers. Charter schools are potentially schools of choice for teachers as well as for parents and students. The charter school concept suggests that allowing teachers to choose schools with educational missions and approaches that closely match their own beliefs and interests promotes a shared professional culture and higher levels of professional autonomy, which should ultimately lead to improved levels of student achievement. Although some charter schools have created and fostered professional opportunities for teachers, the overall evidence on this objective does not suggest that this has been realized. High levels of teacher attrition indicate that teachers are not finding suitable professional learning communities in charter schools. High levels of teacher attrition may, in part, be influenced by the fact that charter school teachers tend to be younger, work longer hours, and receive less pay than teachers in regular public schools.

Advocates believe that charter schools can improve all public schools by sharing innovations and/or through the threat of competition. It is argued that without competition, traditional public schools will not strive to improve. Opponents of charter schools argue that charter schools can hurt traditional public schools by creaming off the less-costly-to-educate students and by forcing limited resources to be split across two parallel school systems. Proponents argued that charter schools could function as public education's research and development sector, and their benefits would extend to traditional public schools that adopted and emulated their innovations. Greater emphasis on innovations was visible in the 1990s, but over time, research indicates, charter schools are not more likely than traditional public schools to innovate.

Some charter school advocates see these schools as laboratories for experiments in the use of privatized services. Proponents argue that increased school choice and privatization will bring a much needed dose of entrepreneurial spirit and a competitive ethos to public education. According to these advocates, schools will run more efficiently by contracting out parts of or all the services they provide. Charter schools, as it turns out, have provided a quick and easy route for privatization as many states allow private schools to convert to public charter schools and most states allow charter schools to contract all or part of their services to private EMOs. While some states have no charter schools operated by EMOs, others, such as Michigan, have more than 80% of their schools operated by EMOs. In 2012, close to 44% of all public charter school students were enrolled in privately managed charter schools. The involvement of EMOs, and the organization of charter schools into networks or franchises headed by an EMO, is counter to one of the early ideals of the charter school movement, namely, that charter schools would be small and locally run.

An argument in favor of charter schools is that they would be high-performing schools where children would learn more. Notwithstanding the pressure for performance on state assessments, a growing body of evidence indicates that charter schools generally perform similarly to demographically matched traditional public schools on standardized tests. States that have better results tend to have fewer for-profit EMO-operated schools, they tend to have fewer charter schools in operation, and they close more poorly performing charter schools.

The research base to support most of these theoretical arguments is largely borrowed from economics and political science; to a large extent, they remain unproven within the education sector. While the research base is still somewhat limited, over time more sound evaluation and research have

replaced the rhetorical or theoretical pieces that earlier dominated the literature on charter schools.

Challenges and Obstacles

Among the biggest challenges that charter schools face are the following:

1. High attrition rates among teachers and administrators
2. Rapid growth of schools in some states, which permitted some less well-prepared applicant groups to open schools
3. Access to school buildings, or at least to low-interest bonds to secure facilities
4. Ability of the schools to direct public resources to instructional costs due to high fees and expenses for the private EMOs
5. Ability to comply with demands for transparency, which is being affected by private management
6. Increasingly polarized support

The charter school ideal has been altered over time, and many agree that the charter school reforms seen today have strayed from the original ideal. There are a number of factors that explain the shift over time, including insufficient or ineffective oversight, insufficient autonomy granted to these schools, insufficient funding to develop new and innovative practices, and increasing involvement by private EMOs that open and drive the growth of these reforms.

Although the purpose and design of charter schools have changed over time, and although charter schools still face considerable obstacles and challenges today, both opponents and proponents recognize that charter schools are now an integral part of our school systems.

Childhood, Concept of

The rationale for any concept of childhood lies, of course, in the idea that childhood is something distinctively different and separate from its Other, which most obviously is adulthood. *Childhood* and *adulthood* have long since formed a contrastive pair, similar to the notion of *young*, which is unthinkable apart from *old*. From the philosophers of Hellenic antiquity to modern psychology, education, and the social sciences, confidence in this distinction has held sway, and across centuries, various *conceptions* of childhood have been produced based on particular views about childhood's difference from adulthood. These conceptions, especially the views on childhood created in modern developmental psychology, continue to influence educational thinking and pedagogical practice in both educational and other institutions involved in things such as social work, health care, and jurisdiction. To a great extent, however, sociologists and anthropologists have relied on dominant psychological notions of childhood. Only fairly recently, in tandem with the increasing interest in the social conditions and the rights of children worldwide, has there been critique of the dominant understanding, followed by reconceptualization.

Childhood is an ambiguous concept. While obviously there is an important difference between *children* and *childhood*, surprisingly often these two are conflated. The belief seems to be that a concept of childhood is created by answering the question What is the child? The more central concept of the two is *the child*, and *childhood* seems to have taken meaning on the basis of particular understandings of this concept. Most definitions of childhood operate in this way, in both scholarly literature and our common everyday knowledge. The Oxford English Dictionary, for instance, defines childhood as "the state or stage of life of a child; the time during which one is a child." Only fairly recently, in the multidisciplinary ("new") field of childhood studies, has a clear conceptual distinction between children and childhood been introduced.

The following sections introduce five ways of conceptualizing childhood as they have been developed and used in the social science field: (1) the

stage concept, (2) the developmental concept, (3) the socialization concept, (4) the everyday-world concept, and (5) the structural concept.

The Stage Concept of Childhood

Earliest Western notions of childhood were based on schematic divisions of human life into a number of "Ages of Life," from birth to death. According to Aristotle, for instance, all living things traverse an arc of three ages: (1) *augmentum*, (2) *status*, and (3) *decrementum*; Shakespeare (in *As You Like It*, 1623) divided the life cycle into seven stages.

The *stage* notion of human life, ingrained in traditional wisdom, has long been the prototypical form of thinking about childhood. Both John Locke and Jean-Jacques Rousseau relied on the stage notion of childhood, although in opposing ways. For Locke, the child was a blank slate (*tabula rasa*), and childhood was the coming to reason of this child as perception and experience fill his mind (*An Essay Concerning Human Understanding*, 1690). Rousseau, in contrast, proposed (*Émile*, 1762) an "authentic" child that has an innate capacity for reason. For both thinkers, childhood was to be seen as qualitatively different from other stages in the life cycle of the human being, and both also gave instruction on how the child should be educated.

Childhood became the object of scientific investigations in the second half of the 19th century. Child study was initially motivated by the quest to discover the origins and specificities of the mind of the human *adult*. The theory of the time was *cultural recapitulation*, originally proposed by Ernst Haeckel, the idea that in the course of his development over a lifetime (ontogeny) the individual repeats the patterns and stages exhibited by the evolution of the species ("ontogeny recapitulates phylogeny"). Accordingly, because children, relative to the adult, were seen as intellectually immature, incomplete, and lacking, it was believed that by studying the child the necessary steps for subsequent development toward full maturity (adulthood) could be revealed. Charles Darwin (himself not an advocate of the recapitulation thesis) was one of the first to write systematic notes on the changes that he observed in his own son (*Biographical Sketch of an Infant*, 1877), his interest being in the relative contributions of a child's inherited endowment and the child's environmental experience.

In time, the recapitulation theory was abandoned, but the idea of "progress," or "development," taking place in the lifetime of the individual, and especially during the time of childhood, was retained, and it came to form the basis of the emerging "child sciences"—first pediatrics and child psychiatry, and later developmental psychology. The specific idea of childhood *development* has had a strong impact also on other social science disciplines inasmuch as they became concerned about children and childhood.

The Developmental Concept of Childhood

The dominant notion of childhood in the late 18th century and since then is that of being in the state of development toward adulthood. The concept of *development* was the foundational basis for the new discipline of developmental psychology. It was understood to be not just a neutral term for the biological and psychological changes that occur in human beings over time. Besides constant change, development implies a particular *direction*, *improvement* (progress), and *goal* (or end point)—of change. The goal of childhood in this conceptualization is to reach mature, autonomous adulthood; to be a child is to be not mature, not yet mature, and in the process of *becoming* mature. Thus, developmental psychology sought to identify orderly sequences of progressive change in the child as he is "growing up," aiming at discovering universal, context-independent stages, and phases of development along various dimensions. The practical goal was to establish chronological (age-related) group norms and milestones of progress for the journey of the young through this childhood phase.

Sigmund Freud's model of psychosexual development, Jean Piaget's model of cognitive development, and Lawrence Kohlberg's model of moral development are based on the developmental concept of childhood: In their theories, they have posited universal stage progressions from a primal, egocentric child to an autonomous adult.

In the most recent three to four decades, the *universalist* position on child development has been firmly contested by arguing that the child's development is inextricably bound up with his sociocultural conditions and changes: Development emanates from the interplay between the child, his immediate environment, and the larger contexts in which the child and the setting are embedded. Any valid concept of child development cannot be but a *contextual* one. Consequently, the normalizing elements of the universalist position ("normal" development and its milestones) have to be questioned.

Contextualist conceptions of child development are being developed, especially by scholars related to the cultural-historical school and the Vygotskian tradition. However, the debate on what drives children's development—the nature/nurture debate—has not been settled within developmental psychology.

A second strand of critique has been concerned with the idea of development itself, not just the context in which development occurs. Based on new knowledge about the variability of children's lives globally and as revealed in historical studies of childhood, and influenced as well by postmodern epistemologies, the argument has gained favor that development and childhood are social and cultural "inventions" or "constructions," and Western constructions at that. This antidevelopmental and antiprogressivist critique of the developmentalism deeply ingrained in the psychology of childhood has yet to produce its own (postdevelopmental?) alternative to the dominant conceptions of childhood.

Childhood as Socialization

Socialization has existed in sociology as the counterpart of the concept of development since the early days of the discipline. Just as the developmental concept depicts the child as not mature, not yet mature, and in the process of *becoming* mature (adult), the concept of socialization retains all these characteristics. The essential difference between the two notions is the greater focus of the latter on the societal (social, cultural) factors that make a child's development (socialization) take place. Similar thinking also has been prevalent in anthropology, where *enculturation* is the corresponding term.

The French early-20th-century sociologist Émile Durkheim is considered the founder of the idea of socialization. Generally, sociology has been noted for its marginal interest in children and childhood, for as Chris Jenks (1982) writes, "social theorists have systematically endeavoured to constitute a view of the child that is compatible with their particular visions of social life" (p. 9). This holds also for Durkheim—the concept of socialization emerged as a corollary of his theory of (adult) society. According to Durkheim (1911/1956), *socialization* refers to the social forces that make social life possible by drawing people together into a community, and it is specifically exercised (especially through education) on "those that are not ready for social life" (p. 71). The constraining effect of socialization on individuals takes place through their "internalization" of social "facts" that originally are external to and independent of them. Thus, in Durkheim's thinking, there is a psychological aspect (internalization) to the social process of socialization.

In the 1940s and 1950s, the American social theorist Talcott Parsons (1951) adopted the notion of socialization to account for the mechanisms by which societies deal with "what has sometimes been called the 'barbarian invasion' of the stream of new born infants" (p. 208). In his systemic and functionalist theory of social life, children are conceived as being a threat to society, and they must therefore be appropriated and shaped to fit in. In this case, the socialization of children is effected by laying down in childhood the major value orientation patterns of society.

Critiques of overly functionalist and deterministic conceptions of childhood socialization developed since the 1970s, particularly in North American social psychology. New approaches to socialization were inspired by interpretive approaches (symbolic interactionism, ethnomethodology) that involved seeing socialization as a complicated process of interaction. In contrast to earlier conceptions, children were no longer seen as passive targets of "agents" of socialization (e.g., family, school) but, rather, were viewed as active partners.

The Everyday-World Concept of Childhood

Still, until the 1980s, "socialization" functioned as the main conceptual tool for social scientists to address children and childhood. Similar to the anti- and postdevelopmentalist trends that challenged the progressivist and universalist notions in developmental psychology, within sociology a critique on socialization has grown since the 1980s and has led to theoretical reconceptualization.

The "rediscovery of childhood in sociology" (Corsaro, 2005) was based not only on the increasing critique of the individualistic and forward-looking connotation of dominant concepts of socialization. There was also a growing confidence in the innovative and creative aspects of children's participation in social life, confirmed in new studies on the competences of infants and young children. Building on earlier phenomenological thinking about children's role in everyday interaction, and increasingly fed by postpositivist epistemologies, especially social constructionism, and fueled by new historical and anthropological knowledge about the enormous variability of children's lives across time

and place, the new conceptualization of childhood was in terms of a *social construction*.

With confidence in the active participation of children in the construction of their everyday lives, the constructionist concept of childhood took its meaning to refer to children's active everyday lives in all their dimensions: their activities, interactions, experiences, beliefs, and so on. Seen to be involved in the daily "construction" of their own and other people's everyday relationships and life trajectories, children as "social actors" became the new conceptualization of childhood. This is also the key orientation of the "new paradigm for the sociology of childhood" proposed in the beginning of the 1990s (James & Prout, 1997). Conceptualizing every child now as a social actor implied, moreover, that each child has his or her own unique childhood; thus, there is a plurality of childhoods for researchers to study.

The Structural Concept of Childhood

A second conception of childhood has been developed within the ("new") sociology of childhood: childhood conceptualized as a structurally formed (or "constructed") social space for children to inhabit (Qvortrup, Bardy, Sgritta, & Wintersberger, 1994). This conception implies the existence in a society of a relatively permanent social category ("children"), and a social and political status that goes with occupancy of the culturally, politically, economically constructed childhood space, in whatever way the category is defined in a particular society.

The structural concept of childhood thus indicates that childhood is a constant feature of the structure of society, comparable with, for example, social class or gender, with which it necessarily intersects. For the inhabitants of the childhood space (i.e., children), any historical childhood is, of course, temporary, for children enter the space at birth (if not earlier) and grow out of it as they enter the next category, but childhood remains.

Hence, childhood as a structural category is also a *generational* category (and concept) that can exist, as both a concept and a social space, only in relation to other generational categories, most obviously the category of adulthood. Thus, both childhood and adulthood, as structural categories, are usefully conceptualized as sets of interrelated social, cultural, political, and economic relations (Alanen & Mayall, 2001; Qvortrup et al., 1994). The usefulness of this conceptualization is in its assistance to researchers of educational issues as they extend their focus beyond psychology and sociology to cultural, political, and economic studies.

Children's Rights

Whether children should have rights, what it means to attribute rights to them, and which rights—if any—are appropriate for children are contentious questions among philosophers who write on this topic. An easy response is that children have their rights specified in the United Nations Convention on

the Rights of the Child (UNCRC), on the grounds presented in the convention and that a child is any person younger than 18 years, except where national law stipulates otherwise. This easy response sidesteps persistent lines of debate about matters such as the purpose and meaning of rights, the moral status of children, and the relationship between *legal* (or *positive*) rights and *moral* (or *fundamental*) rights. Children do have legal rights; they have them by virtue of international law and, in many countries, through national legislation and jurisprudence. The question at issue is whether, when, and why it is appropriate to attribute fundamental human rights to children. This entry sketches a brief history of children's rights and presents some central concepts and lines of dispute about the existence, content, and scope of children's fundamental rights.

Historical Overview

Although the notion of children's rights appeared as early as 1796 with the publication of Thomas Spence's *The Rights of Infants*, only in the late 19th and early 20th centuries did children come to be widely regarded as putative rights bearers. This change accompanied a gradual change in children's moral status from property to persons. Protection rights, the first category of children's rights to emerge, had their roots in the child-saving practices toward the end of the 19th century, when philanthropic and state agencies in Europe and North America began to intervene in family life to ensure the health and welfare of children. Early in the 20th century, partly in response to these social reform movements, children were accorded the status of future persons in need of protection and nurturance. The Geneva Declaration of the Rights of the Child of 1924 epitomized this approach, as did the United Nations Declaration of the Rights of the Child in 1959. Neither had legal force, and both were paternalistic in assuming that parents or other authority figures best determine children's present and future interests.

In the second half of the 20th century, as part of a global movement for the extension of human rights, children were accorded the status of existing persons with qualified rights to self-determination. The UNCRC, approved by the United Nations General Assembly in 1989, is a legally binding international treaty that recognizes children's self-determination rights in relation to their evolving capacities, as well as their rights to protection and nurturance.

Categorizing Rights

Philosophers typically distinguish two categories of rights: (1) a*gency rights* (also called autonomy or self-determination rights) and (2) *welfare rights* (also called social rights). Agency rights involve their bearers in making reasoned choices about how to act; welfare rights entitle their bearers to crucial sources of well-being, such as health care, shelter, and education. A different categorization, used in histories of human rights and in international law, distinguishes between *civil*, *political*, *and social rights*. On further analysis, these three categories can be reduced to two. Civil and political rights safeguard choice and are thus agency rights; social rights safeguard conditions for well-being and are thus welfare rights.

Another categorization, used solely with respect to children, distinguishes *provision*, *protection*, *and participation* rights. Among the proponents of children's rights, one criticism of this categorization is that it involves a category mistake arising from a misreading of the UNCRC and its supporting documents: "provision," "protection," and "participation" refer not to kinds of rights but to central principles of the UNCRC and to the articles that give expression to them. Another criticism presupposes that children's rights are a recent step in the expansion of the scope of human rights. If so, then, it is inconsistent to use one set of terms for children and another for adults. Also, on the face of it, the "3-P" categorization suggests that children's rights are not human rights and, thus, that children do not count as humans in the relevant respects.

How different theorists categorize rights depends on their purpose in doing so. For example, a distinction between agency and welfare rights may serve as a first move in defending the claim that while children do have some rights, they do not have the same rights as adults. Conceptualizing children's rights as human rights enables a comparison of the status and history of children's rights against the rights of other people and leads to the observation that women and Black people were once also denied rights, on grounds similar to those used to deny children moral status as rights bearers.

Should Children Have Rights?

Two opposing conceptions of rights lie at the heart of philosophical disputes about children's rights. On the one hand, rights serve to protect the *choices* of rights bearers; on the other, rights serve to protect important *interests*. The *choice* (or will) theory underpins

much of the skepticism about the attribution of moral rights to children. Although the *interest* theory provides a stronger foundation for children's rights, it need not imply that children should have equal rights with adults. It can instead support the conclusion that children should have rights appropriate to their evolving capacities and to their status as children.

Autonomy, agency, and capacity are pivotal notions in disputes about children's rights, as illustrated in two contrasting images of childhood: the "competent or autonomous child" and the "incompetent or dependent child." Both images figure in the UNCRC, with the dependent child as the subject of so-called protection rights and the autonomous child as the bearer of so-called participation rights. They figure, too, in controversies about the scope and moral weight of children's rights.

Skeptical Views

Several different lines of argument support the view that it is wrong to ascribe rights to children or, more modestly, that children cannot be bearers of agency rights. Three will be outlined here. Call them the arguments *from capacity*, *from the nature of childhood*, and *to consequences*.

The argument from capacity assumes that people cannot and should not have moral rights unless they have the requisite capacities. Capacity is a central idea in the choice theory of rights, which assumes that persons are rational, moral agents whose dignity and equality rest in their freedom to act for reasons. From this perspective, children cannot possess rights, as they do not yet have the cognitive and volitional abilities required for making and acting on rational choices. Capacity is at issue in a second way. Regardless of whether rights are seen as protecting choice or protecting interests, the content of many rights implies specific capacities. For example, a being that is incapable of speech cannot meaningfully be said to have a right to free speech. Self-determination rights depend on capacity; welfare rights arguably do not. Skeptics about children's rights argue that children—or at least young children—lack crucial abilities, such as knowing how to obtain relevant information and handle it systematically, appreciating the significance and consequences of different options, and being able to act in light of consistent values and stable beliefs. On the choice theory, arguments from capacity deny that children can be rights holders at all; on the interest theory, arguments from capacity grant that children have welfare rights, but they disqualify children from holding the same agency rights as adults.

Arguments from the nature of childhood come in several versions, only one of which will be considered here. In a much cited article, Onora O'Neill contends that an understanding of what adults morally owe to children is properly grounded not in rights but in obligations. Two different kinds of obligation—perfect and imperfect—pertain to the relationship of adults to children. Perfect obligations have corresponding rights; imperfect obligations do not. A *perfect obligation* completely specifies to whom the obligation is owed and what is owed to them. For example, a *universal perfect obligation* to all children requires adults to refrain from abusing children. A *specific perfect obligation* is one owed to specified children by specified agents, such as social workers who have undertaken to care for specified children. *Imperfect obligations* require us to do or refrain from doing some action for unspecified others but not for all others. An example is the obligation for adults to be kind and caring in dealing with children. While this obligation may be binding on all adults, it cannot be one that we owe to all children because what is involved in meeting the obligation depends on the circumstances. A *fundamental imperfect obligation* leaves open both how it is to be enacted and for whom. It thus cannot be correlated with a corresponding right. According to O'Neill, any view that takes rights as the moral foundation for what is owed to children fails to capture the imperfect duties of care and concern that are necessary for protecting and valuing children's lives. Another version of the argument from the nature of childhood proposes an ethic of care, not rights, as a better way of meeting children's needs.

The argument to consequences considers what would follow from granting rights to children. It rests on the idea that to pursue their goals and lead valuable lives, adults must have certain character traits and capacities, which are acquired during childhood through proper upbringing and discipline. Granting children freedom to exercise their rights undermines these preconditions for their having fulfilling adult lives. Such license, it is argued, has adverse consequences not only for the children themselves and for the adults they will become but also for the society of which they are members.

Arguments for Children's Rights

Children's vulnerability to harm and neglect and their dependency on adults for care have a moral

urgency that may seem best addressed by ascribing rights to children. But an appeal to children's high vulnerability and dependency could as well be grounds for an ethics of care. A more forceful argument is that human rights are universal and apply to all humans regardless of race, gender, age, or ability, even though historically, women and Black people, and now children, have had to struggle for recognition as rights bearers and persons. This view takes respect for human dignity as the central idea in the attribution of rights; to deny fundamental rights to a person casts doubt not only on her dignity but also on her independent moral standing. However, even if respect for human dignity is taken as the sole warrant for children's rights, the skeptical arguments still require a response.

Rebuttals of the argument from capacity can deny that capacity is a qualifying condition for rights or may grant that it is but raise questions about the meaning, reach, and acquisition of capacity. Those who deny capacity as a qualifying condition commonly claim that humanity is all that is required for moral recognition as a rights bearer. Another line of argument rejects the centrality of capacity in rights talk on the grounds that it protects powerful elites and so reinforces existing social hierarchies.

Suppose, however, that a proponent of children's rights acknowledges, as many do, that some kinds of rights depend on those capacities involved in making choices and acting on them, then the argument from capacity is not yet answered. One answer grants that children, especially young children, do not have the necessary capacities for self-determination rights, but it suggests that they will acquire capacity only through the (appropriately guided) exercise of their rights. To deny children their rights, then, is to keep children in a state of dependence and hinder their development into mature adults able to exercise choice responsibly. A second answer is that children, even very young infants, do have the capacity for choice, where this is understood as being able to express preferences. The skeptic can concede that even infants express preferences but argue that one cannot be a rights holder without an ability to understand and appreciate the significance of the options facing one. Of course, many adults do not meet this more demanding standard of capacity, and yet we do not, on these grounds, deny that they have self-determination rights.

Capacity is not an all-or-nothing affair, entirely absent or fully present. The notion of evolving capacities underpins the UNCRC and is presupposed by gradualist conceptions of children's rights. Gradualism, in its various forms, acknowledges the child both as a person now and as the future person she will become. One form of gradualism suggests that children move progressively from a situation in which their rights primarily protect their interests to one in which their rights primarily protect their choices. It is consistent with a gradualist account that children be given opportunities to exercise choice and participate in decisions affecting them, in ways appropriate to their current levels of maturity and capacity. Education has an important role to play here. On a gradualist account, while children and adults have some rights in common, there are important differences in kind between the rights of children and those of adults.

A rebuttal of the argument from the nature of childhood concedes the importance of imperfect obligations in the relationship between adults and children, particularly parents and their children, but denies that this rules out children's rights. Care and rights are not in competition. Seeing children as rights holders shapes and constrains our actions regarding them and in familial relationships helps form appropriate enactments of love and care.

Rebuttals of the argument to consequences may grant that to pursue their goals and lead valuable lives, adults must have certain dispositions and capacities, which are acquired during childhood through proper nurture, support, and discipline. The view that children's rights undermine these conditions is open to three criticisms: (1) it applies only to agency or self-determination rights, not to welfare rights; (2) it conflates children's rights with license for children to do as they please; and (3) it fails to recognize that the enabling dispositions and required capacities may be acquired through children's exercise of circumscribed agency rights.

On balance, while choice theory captures the sorts of rights that autonomous agents have, interest theory is equally coherent and justifies the attribution of rights to children. Acknowledging children as rights bearers draws attention to their independent moral standing and human dignity.

Chinese Philosophical Traditions and Education

See Confucius

Chomsky, Noam

Avram Noam Chomsky (1928–) is a theoretical linguist, philosopher, and social critic. His 1957 book, *Syntactic Structures*, proposed a theory of grammar that led to the transformation of the field of linguistics and has also been an important stimulus in the areas of education concerned with language acquisition. However, he is more popularly known as a political commentator and dissident who constructs detailed, evidence-driven critiques of the exercise of power by political elites, the mass media, corporate capitalism, and the state, often focusing on the foreign policy of the United States. This aspect of his work also has important implications for the curriculum and conduct of education. In sum, as a result of the range and influence of his thought, Chomsky has been described as the most important intellectual alive today. This entry describes the essence of both prongs of his work and its implications for education.

Chomsky's parents were immigrants from Russia and middle-class Hebrew schoolteachers. His father was also a scholar of medieval Hebrew. Chomsky attended an experimental elementary school, Oak Lane Country Day School, whose founders were involved in the progressive education movement and were influenced by the educational philosophy of John Dewey. As a young man, Chomsky was involved in a branch of the Zionist movement focused on socialist binationalism and Arab–Jewish cooperation.

He attended the University of Pennsylvania, where he received his BA (1949), MA (1951), and PhD (1955). He joined the faculty of the Massachusetts Institute of Technology in 1955 and was appointed as full-time professor in 1965. During the course of a distinguished career, he has received numerous honors for his scholarship, including more than 25 honorary degrees.

Chomsky's early research in linguistics sparked a paradigmatic revolution in the field. Structural linguistics, which originated in the early 20th century, was a classificatory science focused on organizing the basic elements of human languages. Research methods in the field were based on the assumptions of philosophical positivism. Structural linguistics treated language as a static system of interconnected units; the basic approach was to examine a selected "corpus of utterances" in an attempt to classify the elements of the corpus into different linguistic levels (e.g., phonemes, morphemes, etc.). Chomsky argued that while this approach was adequate for phonology and morphology, it was inadequate for explaining sentences (syntax). His critiques of structural linguistics led to the development of generative grammar, which shifted the subject matter of the field to speakers' linguistic competence or their knowledge of how to create and understand sentences. As a result, the goal of linguistics was transformed from the classification of language elements to the creation of a set of rules that could generate all sentences of a language and ultimately explain all linguistic relationships between the sound system and the meaning system of a language.

Chomsky's theories derive from two fundamental observations of language: (1) grammar describes the basic knowledge shared by all speakers of a language and (2) the human use of language is fundamentally creative. He argues that the properties of generative grammar come from an "innate" universal grammar; that is, all languages have the same basic principles and are genetically determined. Language acquisition then is not a matter of habit or sensory experience (e.g., children imitating sounds, repeating words, and responding to positive and negative reinforcement, as behaviorist theories would have it). Rather, in Chomsky's view, humans have an instinctive mental capacity that enables them to learn and

produce language without being taught. From this theoretical vantage point, in 1959, Chomsky wrote an important critical review—widely regarded as devastating—of the behaviorist B. F. Skinner's theory of language acquisition.

Chomsky's political views fall into the broad category of anarchism, which opposes authority, coercion, or hierarchical organization in human relations. Chomsky has described himself as a libertarian socialist. He believes that there is a fundamental need in human nature for creative work and inquiry that are not arbitrarily limited by coercive institutions. His vision of a social order that would maximize this fundamental human characteristic is a federated, decentralized system of free associations that incorporate economic and social institutions, or what has been called anarcho-syndicalism. His political agenda might be described as seeking out forms of authority and domination and challenging their legitimacy. Chomsky has stated that beyond some tenuous points of contact, he sees no intellectually convincing connections between his anarchist political convictions and his scholarship on human intelligence.

Chomsky the political dissident first came into the public eye when he spoke at a protest against the Vietnam War on the Boston Common in October 1965. But it was his 1967 article "The Responsibility of Intellectuals," originally published in *The New York Review of Books*, that established him as the leading American intellectual in the antiwar movement. His book *American Power and the New Mandarins* (Chomsky, 1969) was one of the earliest and most significant works of social and political thought to emerge from the Vietnam War era. His antiwar activism resulted in several arrests and associated him with the New Left Movement, of which he was generally critical. The former U.S. president Richard Nixon included Chomsky on his infamous "Enemies List."

In the 1980s, Chomsky began to examine and write about the media and democracy. *Manufacturing Consent* (written with Edward Herman) is a political economy of the mass media that proposes a "propaganda model" to describe how money and power filter the news in ways that marginalize dissent and allow government and corporate capitalist interests to propagandize the public. His book *Necessary Illusions: Thought Control in Democratic Societies* deconstructs representative democracy, illustrating how capitalist elites control the state while the public merely observes. In practice, democracy becomes a system of elite decision making and public ratification, or what he calls "spectator democracy." Correspondingly, the dominant interests view popular involvement in public policymaking as a threat. Chomsky argues that indoctrination of the political class and diversion of the masses make up the essence of democracy as practiced in the United States.

Based on his political philosophy and his assessments of the mass media and government, it is not surprising that Chomsky has described education, or more particularly schooling, as a system of imposed ignorance. He argues that, like the mass media, schools succeed in domesticating youth by operating within a propaganda framework that has the effect of distorting or suppressing unwanted ideas and information and creating "necessary illusions" and "emotionally potent oversimplifications" to keep people isolated from important issues. Questions that are offensive or embarrassing to the doctrinal systems are ignored. Information that is inconvenient is suppressed.

Chomsky has argued that if schools were serving public (as opposed to private) interests, they would be providing students with techniques of intellectual self-defense so that they could protect themselves from manipulation and control. Chomsky has recalled his own early education in a progressive school as an example of this—a school where children were encouraged to study and investigate as a process of discovering the truth for themselves.

Church and State

The relationship of church and state—or, more broadly, religion and state—is crucial to educational theory and philosophy in light of the profound impact that religious freedom can have on the structure and content of education, including civic education, in a particular society.

There is no fixed or natural relation between religion and state. Globally, religion and state are related in diverse and complicated ways that produce widely divergent levels of religious freedom. States that establish (i.e., legally promote, protect, or favor) one or more religions may strictly punish deviance from the state religion (as in Saudi Arabia) or they may protect the religious freedom of all citizens (as in the United Kingdom). Some states without established religions nevertheless place tight restrictions on religious practices (as in China), while others allow a much wider array of religious liberties (as in the United States). In most cases, civic and/or religious education in state schools is designed to perpetuate the existing relationship of religion and state, whatever that relationship may be.

This entry focuses on the United States, where the legal, philosophical, and cultural contours of church–state relations are primarily guided by three core principles in the federal constitution: (1) nonestablishment, (2) free exercise, and (3) equal protection. After a brief prelude in constitutional history, these core principles are examined in light of their legal application to public and private education.

Constitutional Development

During the tumultuous 15 years after declaring independence in 1776, Americans fought a revolutionary war (1776–1783), ratified 13 state constitutions, and created two national governments, the first of which, outlined in the Articles of Confederation, lasted only eight years (1781–1789). Constant debate during this period about the form of government best suited to a free people eventually led to the ratification of the federal Constitution (1789) and Bill of Rights (1791), which set in motion the first secular nation-state, a country without an established religion.

Though the Declaration of Independence, written primarily by Thomas Jefferson, offers no legal framework or systematic theory of church and state, it nonetheless posits a particular relationship between religion and government. According to this view, "unalienable" human rights are "endowed by their Creator," but governments are nonetheless human institutions whose authority and power are derived from "the consent of the governed" themselves, not from God. The latter concept is known as "popular sovereignty," which President Abraham Lincoln would famously describe nearly 100 years later as "government of the people, by the people and for the people."

If the Declaration promises liberal democracy and popular sovereignty, the Constitution and its Bill of Rights attempt to actualize that promise. Essential to that promise is the First Amendment, which reads in its entirety, "Congress shall make no law respecting an establishment of religion, nor prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the Government for a redress of grievances." The first 16 words, known as the religion clauses, provided the legal framework for religious freedom in the United States by preventing the new federal government from establishing a national religion and by protecting the right of citizens to follow any religion they chose (or none at all).

Several U.S. states retained their religious establishments well into the 19th century; Massachusetts was the last to disestablish, in 1833. This was possible because, on its face, the First Amendment merely bans Congress from making a law "respecting an establishment of religion," and so on; states were free to enhance or abridge the rights named in the Bill of Rights because American citizenship was granted through the states, not the federal government. The Fourteenth Amendment, ratified in 1868, federalized citizenship to grant civil and political rights to former slaves. Since the 1940s, the U.S. Supreme Court has interpreted the Fourteenth Amendment as a guarantee to all persons of the rights enumerated in the federal Constitution and its amendments, so that the First Amendment's establishment clause applies to all officials in all branches of all levels of government, and its free exercise clause applies to all persons living in the United States.

The two religion clauses are related but distinct from one another, and the modern Supreme Court has built separate fields of jurisprudence around each of them. The establishment clause prohibits the government from discriminating in favor of religious beliefs or practices by adopting or endorsing them through its laws or the actions of its employees; the free exercise clause prohibits the government from

discriminating against the religious beliefs or practices of individuals and organizations. The principles are complementary in that nonestablishment applies to government action while free exercise applies to private action. But they are also in tension because an expansive interpretation of one clause often requires a restrained interpretation of the other. For example, allowing the widest range of religious practices (strong free exercise) might require special accommodations for religious people that are not granted to nonreligious people (a position contrary to the strong nonestablishment provisions).

Because the Supreme Court is the final interpreter of Constitutional rights that affect all citizens, its decisions can have enormous social and legal consequences, especially in the realm of education, where establishment and free exercise cases are common. In fact, the legal scholar John Witte has found that a third of the Court's nearly 200 cases on religious freedom since 1817 have dealt with religion and education. Most cases focus on establishment questions regarding religions in public schools, but there are also crucial cases regarding the free exercise rights of teachers and students in public schools and the role of government in religious schools.

Religious Freedom and Public Schools

Given the combination of compulsory education laws and impressionable young students, the legal system takes special care to prevent public schools from endorsing or sponsoring religious perspectives or practices. In two landmark cases that still generate controversy today, the Supreme Court outlawed teacher-led prayers in *Engel v. Vitale* (1962) and teacher-led devotional Bible reading in *Abington v. Schempp* (1963), arguing in both cases that these common practices were clear examples of the state promoting a particular form of religion. The same principle of nonestablishment was applied in the Court's later decisions banning mandatory moments of silence and classroom postings of the Ten Commandments. The Court has also ruled that public schools violate the establishment clause when they invite or allow public prayers or other religious messages during graduation ceremonies, general assemblies, or sporting events—even if the prayers are student led—under the reasoning that students in attendance are coerced into hearing religious messages that they may reasonably infer are endorsed by the state.

The public school curriculum provides another controversial area. Here, a relatively consistent case law has developed that upholds the right of public schools to teach about religions in ways that do not indoctrinate or proselytize but rejects the teaching of religion as scientifically valid. In 1963, the Court noted that teaching about religions in public schools was not only permissible but advisable. "It might well be said," wrote Justice Tom Clark for the Court, that

> one's education is not complete without a study of comparative religion or the history of religion and its relationship to the advancement of civilization. . . . Nothing we have said here indicates that such study of the Bible or of religion, when presented objectively as part of a secular program of education, may not be effected consistently with the First Amendment.

The Court has, however, strongly rebuked schools that present religious views as scientifically valid, as when intelligent design or creation science is taught in biology or when teachers are not allowed to teach evolution. In each case, the Court ruled such activities to be unconstitutional establishment of religion.

Crucial religious freedom concerns also arise from the free exercise rights of students and teachers. Public school students are not bound by the establishment clause, and the Court has ruled that they carry substantial free exercise rights with them so long as their exercise of those rights does not distract from the central educational mission of the school. For example, students may wear clothing with religious messages but not when those messages are hateful; students may be punished for promoting drug use, even if they couch the activity in religious terms. Students are free to read the Bible and pray at school, alone or in groups, as long as the practice is not disruptive to academic work and is not initiated or led by teachers or administrators who, as agents of the state, have limited religious freedom rights at school.

In the past 30 years, the Supreme Court has opened and protected a new avenue for the religious freedom claims of private citizens and organizations based on the Fourteenth Amendment's guarantee of equal protection under the law. In several landmark cases, the Court has ruled that if public universities, secondary schools, or primary schools offer project funding or open their facilities after school hours to nonreligious community groups, religious groups must have equal access.

Religious exemptions pose significant challenges to contemporary legal and educational theory

because they pit free exercise claims against values of nonestablishment and equal treatment. Treating all people equally may actually punish one group more than another, as when a school's ban on hats forces Sikh men and veiled Muslim women to choose between important symbols of their faith or their education. Should some religious practices deserve special exemptions? If so, how should we decide which exemptions are valid or desirable? In 1972, the Supreme Court famously ruled in *Wisconsin v. Yoder* that the Amish community's need to sustain its agricultural way of life provided sufficient religious warrant to exempt their children from compulsory education after the eighth grade. A series of Court decisions and congressional laws beginning with *Employment Division v. Smith* (1990) narrowed, widened, then narrowed again the ability of religious people to claim exemptions from generally applicable law. This remains an active area of First Amendment jurisprudence.

Government Involvement in Religious Schools

If the preponderance of church/state controversies falls on the public schools, private religious schools are also the subject of robust constitutional questions. In the past three decades, the Supreme Court has opened the door to extensive public financial support for religious schools under the principle of equal treatment. It has affirmed the use of publicly funded tuition vouchers to pay for education at religious schools in lieu of public schooling; the state's purchase of computers for religious schools; the use of public funds for remedial education, sign language interpreters, and other services at religious schools and colleges; and the granting of tax deductions to parents who pay private school tuition and other educational expenses. In each case, the state program in question was deemed to provide a benefit or service that was neutral with respect to religion because it was provided to a broad class of citizens defined without reference to religion. Though in effect these laws provide benefits to religious persons or institutions—at times, almost exclusively so—the Court found that their intent was not discriminatory, and thus the benefits passed constitutional muster.

U.S. Supreme Court Cases on Church and State

Agostini v. Felton, 521 U.S. 203 (1997).
The Court's decision in this case explicitly abrogated its earlier Aguilar v. Felton *(1985) opinion that providing on-site services at sectarian schools was not in keeping with the separation of church and state doctrine. In its ruling, the Court acknowledged that not all government aid that directly affects religiously affiliated schools is forbidden.*

Employment Division, Department of Human Services of Oregon v. Smith, 494 U.S. 872 (1990).
The Supreme Court ruled that their religious beliefs do not necessarily exempt people from compliance with neutral, generally applicable laws.

Engel v. Vitale, 370 U.S. 421 (1962).
The Court held that the Establishment Clause precluded the recitation of state-authored prayers in public schools.

Everson v. Board of Education of Ewing Township, 330 U.S. 1 (1947).
The Supreme Court applied the Establishment Clause to the states for the first time in a case involving education, allowing state provision of transportation for parochial school students.

Good News Club v. Milford Central School, 21 F. Supp.2d 147 (N.D.N.Y. 1998) *aff'd,* 202 F3d 502 (2d Cir. 2000); 533 U.S. 98 (2001).
The Supreme Court ruled that a religious group could not be denied the use of a public school's facilities after school hours if the facilities were available to other groups promoting similar issues, namely, the moral and character development of children.

Lamb's Chapel v. Center Moriches Union Free School District, 508 U.S. 384 (1993).
The Supreme Court ruled that a school board's denial of school facility use to a religious group violated the group's First Amendment guarantee to free speech.

Lemon v. Kurtzman, 403 U.S. 602 (1971).
Lemon v. Kurtzman *or "Lemon I," is best known for its three-part test, which the Supreme Court created to be*

used in evaluating whether government action violates the Establishment Clause; this provision prohibits the government from making laws "respecting an establishment of religion." The three parts of the "Lemon test" are that (1) a statute or program must have a secular legislative purpose, (2) its principal or primary effect must be one that neither advances nor inhibits religion, and (3) it must not foster excessive government entanglement with religion.

Mitchell v. Helms, 530 U.S. 793 (2000).

The Supreme Court held that a federal program that loaned instructional materials and equipment to schools, including those that were religiously affiliated, was permissible under the Establishment Clause of the First Amendment of the U.S. Constitution.

School District of Abington Township v. Schempp, 374 U.S. 203 (1963).

In a landmark judgment, the Court held that public schools cannot require devotional Bible reading or collective spoken prayers, even if parents may exempt their children, because these activities are essentially religious ceremonies in violation of the Establishment Clause. The Court affirmed, however, the study of religion and the Bible in public schools "when presented objectively as part of a secular program of education."

Wisconsin v. Yoder, 406 U.S. 205 (1972)

Wisconsin v. Yoder *upheld the Fourteenth Amendment right of parents to direct the education of their children.*

Zelman v. Simmons-Harris, 536 U.S. 639 (2002).

The Supreme Court upheld the constitutionality of a program from Ohio that provided educational vouchers for children from poor families, because it offered aid pursuant to neutral secular criteria that neither favored nor disfavored religion, was available to religious and secular beneficiaries, and was available to parents based on their own independent, private choices.

Cicero

The Roman statesman Marcus Tullius Cicero (106–43 BCE) was considered one of the greatest orators of antiquity, and his writing—on rhetorical theory, government, ethics, philosophy, law, and other topics—remains influential today. Cicero was a politician who put his ideas into practice, but he also wrote extensively about his theories. Much of his writing survives, including hundreds of letters, dozens of speeches, and several treatises on a variety of topics. Among the more noteworthy of his surviving texts is *De oratore*, or *On the Orator*, in which he argues that an ideal orator is master of all communication, written and oral. Cicero synthesized rhetoric and philosophy, arguing that the ideal orator—whether communicating via speaking or writing—needed to be knowledgeable about various subjects, including law, history, and philosophy. Cicero's *De oratore* and other works were influential not only among educators in Rome, such as Quintilian, but also throughout history, notably during the Renaissance. His writings on political theory influenced the founding fathers of the United States and the leaders of the French Revolution. His impact on prose style and political thinking can be felt today.

Oratory in Practice

Cicero was born into the equestrian order (the upper middle class) during a time in which statesmen typically came from the patrician order (or aristocracy). It was possible, however, for a nonpatrician to rise high politically, which Cicero did by first developing a reputation as an eloquent speaker in the courts before winning elections to several offices. He achieved the highest office possible, that of consul (comparable to the U.S. president), in 63 BCE, and he remained an influential senator afterward. He lived during a volatile political time in which the democratic Republic was losing power.

Cicero opposed the dictatorship of Julius Caesar, but he was not asked to participate in Caesar's assassination and was not present when it took place in the Senate chambers in 44 BCE. Afterward, Cicero publicly derided Mark Antony, who seemed likely to follow in Caesar's footsteps. He supported Octavian, Caesar's named successor, in the hope that the young man would leave governing to the elected representatives. In the wake of Caesar's death, a series of civil wars occurred as different factions vied for power. During a short-lived truce, Antony convinced Octavian to have Cicero killed. The elder statesman was slain while fleeing the country. It was reported that his head and hands, which had spoken and written such powerful rhetoric, were severed and nailed on display in Rome. Cicero's death has been seen as symbolic, signifying the death of the kind of active, public rhetoric that he promoted. His assassination showed how powerful his words had been but also how powerless public speech was in this new Roman society. Octavian eventually arose from the fighting to become the first emperor of Rome, taking the name Augustus. In his ensuing reign, and the subsequent

reigns of his successors, citizens of Rome were afraid to speak on political issues and participate in public life the way Cicero had.

Rhetorical Theory

Cicero wrote extensively throughout his life. One of his earliest works, titled *De inventio*, or *On Invention*, discussed invention, the first of the five rhetorical canons. As a schoolboy, he would have been educated in all the five canons—(1) *inventio* ("invention"), (2) *dispositio* ("arrangement"), (3) *elocutio* ("style"), (4) *memoria* ("memory"), and (5) *pronuntiatio* ("delivery")—considered necessary for producing a great speech. *De inventio* was possibly Cicero's first attempt at writing about all the five canons; however, either he did not finish the others or they have been lost. Cicero was probably no more than 20 years old when he wrote *De inventio*; it remains noteworthy primarily because of its contrast with *De oratore*, which he wrote some 30 years later, after a successful political career. In style, *De inventio* reads like a textbook for orators speaking in court. Cicero pedantically presents the information but struggles to synthesize the various points of view. Cicero himself later criticized *De inventio* as a youthful writing exercise. Nevertheless, *De inventio* provides insight into Roman rhetorical education in that time period.

De oratore, on the other hand, provides a richer, more eloquent examination of rhetoric and oratory. While *De inventio* was written like an education manual, which was a common format at the time, Cicero chose to break from this trend, modeling *De oratore* after the Greek dialogues. In the vein of Plato's *Gorgias* or *Phaedrus, De oratore*, which is much longer than the Platonic dialogues, consists of a series of fictional conversations between preeminent Roman orators, historical figures from Cicero's youth. By using representations of well-known orators, Cicero was able to provide a theoretical discussion of rhetoric.

Similar to the way Plato represented Socrates, Cicero used the character of Crassus, a former consul who had actually tutored Cicero, as the primary means to express his own point of view. However, Cicero does not entirely disagree with Antonius, the other main character; and furthermore, the participants in the debate modify and amend their perspectives. The dialogues then offer a demonstration of the varying ideals of rhetoric from the time period, but the work as a whole also provides an illustration of effective communication leading to more developed thinking. Because of its structure and style, *De oratore* does not provide a concise thesis regarding Cicero's rhetorical theory. Rather, the discussion implies the flavor of Cicero's perspective of rhetoric. Through *De oratore*, Cicero paints the picture of the ideal orator as someone who achieves excellence in oratory through the study of philosophy and rhetoric. He noted that wit, humor, and psychological insight were important to move an audience to a particular emotion. An orator must be able to adapt his rhetorical style to different occasions or audiences. Moreover, the orator must feel the same emotions that he is trying to arouse in a particular audience.

While Cicero's discussion of rhetoric emphasized oratory, this was a product of Roman society and should not be seen as a preference over writing. Decision making in Rome, whether in a courtroom or in the senate, happened predominantly through verbal public discourse. Written texts, though not necessarily scarce for educated citizens, were certainly rarer than the mass-produced print and digital texts saturating the modern world. Nevertheless, Cicero thought that an orator should be eloquent regardless of the mode of delivery, and his own written treatises and spoken speeches demonstrated that the ideal he argued for could be achieved.

One of the reasons for Cicero's continuing relevance is his discussion of rhetoric, as modern scholars do not treat it simply in terms of oratory but apply it in broader ways. Just as the five canons have been adapted to apply to written and electronic communication, Cicero's discussions of oratory remain relevant to rhetoric in various forms. Considerations of audience, style, arrangement, the rhetorical canons, and even wit and humor remain pertinent to communication in varying contexts, even if society no longer places as much importance on oratory.

Citizenship and Civic Education

Citizenship has a number of different potential meanings, ranging from a person's legal status within a country to his or her civil, political, or social standing within a community, to the set of behaviors that represent a particular ideal of civic virtue. Civic education is hence an equally broad concept. It can cover solely the specific rights and duties of legal citizens, but usually it is used more capaciously to indicate the knowledge, skills, and attitudes that children are expected to learn to be virtuous and civically productive members of society. Citizenship and civic education are key concepts in the philosophy of education because their meanings, aims, and practices are so contested, both among philosophers and among actors on the ground, such as parents, educators, politicians, students, and members of diverse cultural groups. This entry begins by addressing different conceptions of citizenship, including the emerging concepts of digital and global citizenship. It then transitions to the relationship between citizenship and civic education, explaining why civic education is needed and how its aims and functions vary in relation to a country's form of government. Given democracy's global ascendancy, the bulk of the entry discusses why even within democratic contexts there is significant contestation over civic education's purposes and practices. The entry ends by clarifying that civic education takes place in multiple settings, not just schools, although schools do pose particularly interesting challenges to philosophers of education.

What Does It Mean to Be a Citizen?

At its most basic level, citizenship refers to the legal status enjoyed by full members of a state (meaning a self-governing country). Citizens have rights and privileges accorded or protected by the state, as well as duties toward the state. These duties almost always entail paying taxes and following the laws; they may also include serving on a jury, voting, serving in the military, attending church, reporting suspected subversives, or attending rallies, among many other possibilities. Rights and privileges are equally variable, depending on the state's form of government and political traditions. They may include rights or privileges to vote, to be protected from physical attack, to earn a living wage, to speak freely, to attend school, to run for office, to obtain a passport, to practice one's religion, or to travel. Even in democracies, however, not all citizens necessarily share the same rights, duties, or privileges. Before 1971, for example, female citizens of Switzerland did not enjoy the same right to vote in federal elections as male citizens had. Currently, male citizens have the duty in the United States to register for Selective Service, whereas female citizens do not. Gay citizens in most countries do not enjoy the privilege of marrying a same-sex partner. So citizenship is a shared legal status to some extent, but one that may vary depending on individual citizens' identities. At the same time, a number of rights, duties, and privileges are also enjoyed by noncitizens who live within a state. For example, in most states noncitizens are obligated to pay taxes, are provided some social services, and have similar rights to free expression or free assembly as citizens possess. Noncitizens sometimes even have the right to vote.

When philosophers and educators address citizenship or civic education, therefore, they often think of themselves as referring to the identities, rights, and obligations of the residents of a country in general, rather than solely those of legal citizens. It can be helpful to think in terms of the three forms of citizenship—civil, political, and social—distinguished by the sociologist T. H. Marshall. He used this distinction to analyze how citizens' rights have changed over time, but these three forms are equally useful for understanding how citizenship itself is a multidimensional concept, not merely a political status. "Good citizenship" is similarly taken to refer to a broader set of virtues than those characteristic merely of legal citizenship. Civic virtue may be seen in a person's helping out an ailing neighbor or in people working with multinational organizations to improve economic conditions or end child slavery. In this respect, citizenship is sometimes treated as a way of being in the world—of being attentive to the common good or doing one's part—rather than as a way to distinguish a set of people from others on status-dependent grounds.

New forms of citizenship are also coming to the fore that are not connected to state membership or residence. One is the "digital citizen," sometimes referred to as the "netizen." Digital citizenship can refer to how people work through the World Wide Web, across geographic boundaries, to identify injustices or solve problems together. The use of Twitter during the Arab Spring in 2011 was one prominent instance of digital citizenship. Digital citizenship may also refer to the use of digital tools, such as online petitions or automatic data aggregators, to conduct civic and political action solely online. It also increasingly refers to citizens' roles as media producers rather than solely consumers; digital citizens contribute to the creation and dissemination of civic knowledge through posting blogs, videos, and other resources. Or netizens may enact digital citizenship by fighting against Internet trolls and socializing new members into a network. Just as the digital space is in flux, so too is digital citizenship; one can predict, however, that it will be an ever more prominent component of both philosophy and education about citizenship.

A second category of citizenship that transcends state boundaries includes transnational, global, and cosmopolitan citizenship. Transnational citizens have political roots in two or more states, thanks to immigration, refugee status, intermarriage, or other life experiences. They identify with multiple countries. Advocates of global citizenship, by contrast, often deny that they—or anyone—should identify with *any* country; rather, they embrace a vision of citizenship that links all human beings in a collective search for solutions to global problems like climate change or economic inequality. They also embrace a globalized conception of human rights and obligations, rather than one that is state specific. Cosmopolitan citizens may (or may not) also disavow allegiance to any particular country, but this tends to be because they feel connected to many countries and cultures as a result of multicultural production and consumption, work, travel, or the cosmopolitan character of where they live. Thanks to these experiences, the philosopher Kwame Anthony Appiah argues, cosmopolitan citizens embrace the value of pluralism, even if they also hold strong local identities. Martha Nussbaum (2002) pushes the cosmopolitan ideal further toward a global one, arguing that "we should give our first allegiance to no mere form of government, no temporal power, but to the moral community made up by the humanity of all human beings" (p. 7). Cosmopolitan citizenship is often contrasted with patriotic citizenship, a commitment to "my country, right or wrong."

Why Is Civic Education Necessary?

There are two primary reasons why civic education is necessary. First, and perhaps of primary importance for those who do not want to sink into a state of nature (in which life is likely to become "nasty, brutish, and short," as Thomas Hobbes so memorably put it), civic education of some sort is necessary to perpetuate the state itself. No government is intrinsically self-perpetuating, as there is no reason to think that human beings born under any particular government will naturally come to develop the knowledge, skills, and dispositions to maintain it. In the case of an unjust or illegitimate state, civic education may be needed especially to convince or compel its subjects to remain in its thrall. Such an education might play primarily on fear: of a dangerous "other," of social collapse in the absence of the state, or of the state's power to inflict harm on dissenters. In this respect, illegitimate states may also use civic education as a means of maintaining privilege for those in power, and to either justify or obscure the disempowerment of others. A just and legitimate state, however, also needs civic education for its perpetuation. As will be addressed below, citizens in just and legitimate states tend to have many rights and duties. It takes a great deal of work to learn how, when, and why to exercise one's own rights and duties, as well as to respect those of others. To the extent that ordinary citizens are also involved in governing—as they are in a democracy "of the people, by the people, and for the people"—civic education is necessary to teach citizens how to lead.

Second, civic education is necessary to realize the civic ideals of the state, which is different from perpetuating the state itself. Civic ideals that identify the appropriate kinds of relationships among citizens—whether those are of equality, natural hierarchy, mutual respect, shared adoration for the fatherland, mutual noninterference, or common national identity—are achieved only to the extent that citizens internalize and act on these ideals. Civic education is necessary for this internalization and action. Related to this, some thinkers also view civic education as essential for helping people become their ideal selves, insofar as they view civic life as essential to living a good life. Aristotle, for example, declared in Book One, Part II of his *Politics* that "man is by nature a political animal. And he who by

nature and not by mere accident is without a state, is either a bad man or above humanity." This perspective that civic engagement is central to the good life is one that has been developed especially by advocates of civic republicanism, including Niccolò Machiavelli, Montesquieu, and Hannah Arendt.

Civic education is also arguably necessary regardless of state interests. As young people learn to navigate digital citizenship, for example, they may well need guidance about how to do so responsibly, constructively, and safely. Many adults and children alike are concerned about online bullying, for example. Navigating the many different online publics with their own echo chambers of ideas and even simply distinguishing fact from opinion from falsehood when using unmediated digital sources also are skills the development of which may require civic education. Advocates of cosmopolitan or global citizenship also tend to see civic education as being essential to help develop broad-minded, mutually respectful citizens of the world. It also takes a great deal of effort to work across cultural, linguistic, or geographic boundaries to solve problems of collective concern. This kind of practice is an essential component of civic education for global citizenship.

What Are the Goals of Civic Education in a Democracy?

As the sections above have suggested, civic education may have many different goals, depending on the civic institutions that it is intended to serve. Because the majority of countries in the world are democratic in at least some respects however, and because much of the philosophy of education that addresses civic education presumes a democratic context, it is especially important to consider the goals of civic education in a democracy.

To begin with, it is important to acknowledge that many components of a democratic civic education may also be attractive to authoritarians or even tyrants. For example, teaching respect for the law, honesty, literacy, and willingness to sacrifice for the greater good may be essential goals of an effective civic education in either a democracy or an autocracy. On the other hand, some knowledge, skills, and attitudes seem more particular to democracies. The capacity for self-rule, for example, is by definition central to democracy—the original Greek term means "rule by the people." Other aims of democratic civic education might include the development of mutual toleration and respect, commitment to freedom of speech and other core democratic rights and values, acknowledgment of the legitimacy of democratically achieved decisions even if one is on the losing side, the capacity and inclination to deliberate with diverse others, and the ability to recognize and elect good political leaders.

To some extent, which of these aims rises to the fore depends on one's ideal of democracy itself. For example, the capacities for deliberation with diverse others, on the one hand, and for recognizing and electing good leaders, on the other, echo key tensions among advocates of popular democracy, deliberative democracy, and representative democracy. Depending on one's view about what democracy entails—majority rule, deliberative consensus building, or the election of wise representatives who do the actual governing—a democratic civic education may focus on fairly disparate skills and knowledge. Thomas Jefferson (1818/1856) clearly demonstrates this divide in his proposal for public education. He advocates universal primary education on the grounds that every citizen should learn to be economically self-sufficient, "to understand his duties to his neighbors and country," and "to know his rights; to exercise with order and justice those he retains; to choose with discretion" his representatives, and "to notice their conduct with diligence, with candor, and judgment" (p. 434). He advocates higher education for a much smaller number of students, however, "to form the statesmen, legislators and judges on whom public prosperity and individual happiness are so much to depend" (p. 435). Jefferson's vision of civic education clearly distinguishes between the democratic rulers and the democratically ruled. Thirty years later, the American educator Horace Mann (1846/1891) promoted a very different vision of democratic civic education. He warned,

> In a republican [representative] government, legislators are a mirror reflecting the moral countenance of their constituents. And hence it is, that the establishment of a republican government, without well-appointed and efficient means for the universal education of the people, is the most rash and fool-hardy experiment ever tried by man. . . . It may be an easy thing to make a republic; but it is a very laborious thing to make republicans. (pp. 270–271)

Joseph Kahne and Joel Westheimer (2004) have identified a related division in contemporary civic education among proponents of "personally respon-

sible, participatory, and justice-oriented" citizenship (p. 237). They characterize the personally responsible citizen as someone who donates food to a canned food drive, say, while the participatory citizen organizes the food drive. The justice-oriented citizen, in contrast, focuses on addressing the underlying problems of hunger and food scarcity. All three approaches are compatible with democracy, but as Kahne and Westheimer show through both philosophical and empirical analyses, they imply very different agendas for civic education.

To some extent, these differences are rooted in competing civic *identities*. If a person thinks, "As a good citizen, I am someone who . . . ," how should he or she finish the sentence? The debate over patriotic education becomes relevant here. How important is it for someone to declare, "I am proud to be an American [or other nationality]" or "As a good citizen, I am someone who defends my country to the utmost"? Many advocates of patriotic education argue that only such sentiments bind strangers together in a web of reciprocal obligation. Only such sentiments are strong enough to motivate civic engagement and active democratic cooperation in a multicultural context. Others advocate instead that citizens should learn to say, "As a good citizen, I am someone who fights injustice even when that means opposing my own government" or "who defends human rights and battles global climate change." These divisions do not break down neatly along ideological lines. Nonetheless, such disputes raise significant practical challenges for civic educators, who fear teaching a partisan curriculum. Unfortunately, this means that civic education often eschews politics altogether for an anodyne mush of lessons about how a bill becomes a law and controversy-free service learning projects.

Finally, some people question any separation of civic education from the broader educative enterprise. John Dewey (1916/1944) famously characterized democracy as follows: "A democracy is more than a form of government; it is primarily a mode of associated living, of conjoint communicated experience" (p. 87). In this respect, education for democracy and education for life are inextricably intertwined. It does not make sense to conceive of one in the absence of the other. Another reason why civic education may be thought to be inseparable from "good education" is that the strongest predictor of adults' civic and political engagement is their number of years of schooling. This finding has held true for a century in virtually every country that has been studied. Hence, it is possible that civic education understood as education for civic empowerment might best be characterized as high-quality education, period, rather than as specific instruction in the knowledge, skills, and attitudes particular to democratic citizenship.

On the other hand, there is significant evidence of a civic empowerment gap in the United States and other countries between members of historically privileged versus historically disenfranchised groups (Levinson, 2012). One way to address this gap is to work with historically disenfranchised youth to construct an intentionally designed, empowering civic education. Paulo Freire (1970/2008) similarly advocates reshaping education in concert with "the oppressed" to achieve transformative civic ends:

> No pedagogy which is truly liberating can remain distant from the oppressed by treating them as unfortunates and by presenting for their emulation models from among the oppressors. The oppressed must be their own example in the struggle for their redemption. (p. 54)

Where Does Civic Education Take Place?

Civic education takes place throughout society, in public and in private. Civil society is itself educative, through its signs, symbols, and practices. Every coin and bill offers a prominent reminder of the state's civic heroes and values. So, nowadays, do most government websites. Court rooms featuring judges clad in robes and often wigs, police checkpoints, everyday interactions with social service agencies, and the architecture of city halls all teach citizens about the power and nature of the state and where they stand in relation to it—whether for good or ill. Families also engage in civic education, whether intentionally or not. Children are instructed about when and how to speak up and when to keep their heads down and comply with the dictates of others. Some children learn how to exercise leadership in the family or through extracurricular activities. They may learn to debate current events over dinner, accompany their parents to vote on election day, or volunteer at a shelter every month. There is strong evidence that all these kinds of experiences affect the nature, quantity, and quality of their later civic and political engagement as adults. The impact of the family on civic engagement has been recognized for centuries, in fact. Even while women were excluded from most public roles in the United States until the 20th century, for instance, they

were lauded as essential contributors in raising their sons and husbands to support the causes of liberty and democracy.

Just as families and civil society engage in civic education both explicitly and implicitly, so too do schools have multiple ways of providing civic education. The most obvious of these are government, history, and civics courses. There has been an ongoing debate about the impact of such courses. There seems to be good evidence that when these courses are taught very well, including active learning opportunities such as simulations, discussions, and action civics, they can contribute to students' civic knowledge, skills, and engagement. The most important factor is an open classroom climate in which students feel free to express their own opinions and disagree with others in a mutually respectful way. Unfortunately, however, many of these classes feature dry recitations, textbooks, and worksheets that have little demonstrable impact on students' civic learning. As these pedagogical examples suggest, though, schools also provide civic education, whether intentionally or not, more broadly through their overall culture, practices, and pedagogies. Whether or not a student experiences a high-quality civics course, her experiences of participating in student government, feeling respected in the hallway and cafeteria, and being solicited for her opinions in school assemblies can also promote her sense of civic efficacy, membership, and identity. The opposite may also occur in schools that disrespect students or give them few outlets for voice and leadership. As philosophers of education reflect about citizenship and civic education, therefore, this is another realm for productive inquiry.

Code Theory: Basil Bernstein

Basil Bernstein (1924–2000) was a North London schoolteacher turned sociologist of education, appointed to the Karl Mannheim Chair of Sociology of Education at the Institute of Education at the University of London. From the 1960s on, he sought to describe the principles underlying the perpetuation and change of class relations by the family and the school. In a series of five volumes, collectively titled *Class, Codes and Control*, he progressively developed his theory in dialogue with the work of his students. A theory of the code is central to this work. This entry discusses the development of code theory and Bernstein's ideas about sociolinguistic and educational codes.

A *code* in common usage is a covert translation or regulation device linking features in two different contexts. "Cracking the code" entails making visible the principles of the translation device so that one is able to "read" the features of one context in terms of the features of the other. The "genetic code," for example, allows one to read the relation between personal attributes and one's genetic inheritance. To

grasp what is translated or regulated by Bernstein's educational code, three of Bernstein's intellectual forebears merit a brief comment.

After the anthropologist Mary Douglas, an ardent admirer, Bernstein was the most important Durkheimian scholar to come from England. He shared Émile Durkheim's project of understanding how macrosocial relations—the division of labor—both shaped and were shaped by symbolic cultural forms and forms of consciousness through the institutions of the church, family, and school. Bernstein also became steeped in the structuralist and poststructuralist European intellectual currents of the 1960s and 1970s, sharing with them a desire to render legible the invisible social pattern and an inclination to abstraction and formalism, which some readers found off-putting. Paul Atkinson has pointed to the influence of Ferdinand de Saussure, but one could equally point to Noam Chomsky, Jean Piaget, A. R. Luria, and Lev Vygotsky, and also to his intellectual comrade, the linguist Michael Halliday. To conclude that Bernstein was therefore a "structuralist," as many have done, is erroneous. He was also influenced by symbolic interactionism, and in common with the sociologies of his time, his aim was to give an account of the principles of the code in terms of both the structural dimension (hence "class") and the interactional or communication dimension (hence "control").

There are two principal phases of the development of code theory, the first concentrating on the principles of communication generating different "orientations to meaning" (or different sociolinguistic codes) in young children, the second broadening the theory to account for educational communication in general. In the latter development, the theory is refined to show how coding principles vary and how these variations can be formally modeled.

Sociolinguistic Codes

Why, asked Bernstein in 1960s England, was working-class schooling failure so intractable? Which mechanism of mass schooling reproduced the division of labor and the hierarchy between mental and manual labor so remorselessly? How did the class position of parents become transmuted into a cognitive orientation that favored middle-class children and disadvantaged those from working-class homes?

Through a series of ingenious studies, Bernstein identified two critical nodes. The first was the form of socialization in the family, in particular the way parents exercised authority. Bernstein distinguished between modes of parental control. Middle-class socialization relations were predominantly *personal*—where the control was filtered through reason and discursive elaboration ("Why do good children not hit the cat?"); working-class relations were predominantly *imperative*—where the control was more directly exercised through commands and injunctions ("Because I said so"). These socialization styles engendered distinct "habits of meaning," identified through speech repertoires. The imperative mode generated a *restricted code* or orientation to meaning—particularistic, context dependent, more concrete; the personal mode generated an *elaborated code*—universalistic, context independent, more abstract.

Bernstein's point was to show that middle-class socialization, which matched the orientation of the school, gave middle-class children a head start, while working-class children, with their coding mismatch, still had to learn the orientation and associated semantic forms the school assumed had been already learned. The head start was given by the properties of the code, which allowed middle-class children to recognize the task requirements of elaborated discourse at school (possession of the recognition rule) and allowed them to produce a legitimate text or performance (possession of the realization rule). For example, when Lesley Lineker (1977) asked children to explain how to play hide-and-go-seek, middle-class children tended to describe the rules of the game, while working-class children described their particular personal experiences.

The term *restricted* proved to be most unfortunate and was taken by sociolinguists like William Labov to be referring to a deficient dialect rather than a different semantic style, something Labov regarded as a cultural insult. It took a great effort of clarification from Bernstein before Labov was ultimately persuaded, by which time irreparable damage had been done to the theory of sociolinguistic codes.

Educational Codes

So far then, Bernstein had established that it was the possession of a matching coding orientation, tacitly acquired at home, that enabled middle-class children to select and integrate the required meanings and forms of their realization for success at school. He next turned his attention to the modalities of the elaborated code of the school itself, refining his theory to express the axes of variation of the

two principal dimensions of the elaborated code, the *structural* dimension and the *interactional* dimension. From Durkheim, he adopted the term *classification* to denote the degree to which categories of agents, school subjects, and spaces should be kept apart (strong classification) or integrated together; and from Erving Goffman, he adopted the term *framing* to denote the degree to which the communication relations were controlled by the teacher (strong framing) or allowed for apparent control by the children (weak framing). Strength of classification thus regulated the dimension of power; strength of framing regulated the dimension of control. Together, classification and framing values provide the grammar of the educational code—how the principles of power (class) and control are translated in the teaching context into forms of learner consciousness.

In his early work, Bernstein distinguished between strongly classified and framed curricula, which he called collection code or closed curricula, and weakly classified and framed curricula—integrated code or open curricula. Similarly, he distinguished between strongly classified and framed pedagogy—which he called visible pedagogy—and weakly classified and framed pedagogy—invisible pedagogy. In this latter analysis, strong coding values emphasize clarity of expectations and hierarchical differences—between teachers and learners and in the relative performance of learners—while weak coding values foreground the capacities and predispositions of learners and background both hierarchy and expectations.

Two developments characterize his later work. First, the concept of framing has been considerably elaborated. Following Durkheim and Talcott Parsons, Bernstein distinguished between two dimensions of the communicative relationship: (1) a moral or expressive dimension, akin to school climate, which Bernstein called the *regulative discourse* and which was principally exhibited in the way the school was run—more or less strictly—and (2) an instrumental dimension, called *instructional discourse*. The code of instructional discourse—control over transmission of content—determines whether the selection of learning material, its sequencing, its pacing, and its evaluation are strongly controlled or not. The second elaboration is that classification and framing have been allowed to vary independently, which has allowed for a broader number of pedagogical possibilities and has allowed researchers to inquire into the most appropriate combination for learners from different, especially poor and disadvantaged, backgrounds.

The most comprehensive investigation into this feature has come from the work of the Sociological Studies of the Classroom group at the University of Lisbon, led by Ana Morais. They have been able to show that *strong framing* over external content selection and over the evaluative criteria (which signal the performance expectations of the curriculum), together with *weak framing* over pacing (to allow different learners time to catch up) and over teacher–pupil relations (which allows teachers to individualize the teaching), works best for students from both the middle and the working class. Of these, making the evaluative criteria explicit is the most critical. This means telling children unambiguously what is expected of them and what is missing from their answers, and clarifying concepts. This "mixed pedagogy" has been empirically supported by work done in the United States, South Africa, and Australia. The great virtue of this refinement of educational code theory is that it breaks from the hoary ideological polarities of learner-centered versus traditional or back-to-basics pedagogies and allows for precision in stipulating the coding values that offer the best access to school knowledge for disadvantaged children.

Cognitive Load Theory and Learning

Cognitive load theory uses knowledge of human cognitive architecture to generate instructional

procedures. In turn, the structure of human cognitive architecture is based on biological, evolutionary principles. This entry discusses how the principles of natural information processing systems apply to biological evolution and human cognition and what techniques can be used to reduce working memory load and facilitate the transfer of information to long-term memory.

The categorization of knowledge is an important facet of human cognitive architecture. David Geary distinguishes between biologically primary and secondary knowledge. We have evolved to acquire various modules of biologically primary knowledge automatically and without conscious effort or explicit tuition over countless generations. Examples are learning to listen to and speak a first language, recognizing faces, and learning to use a general problem-solving strategy.

Biologically secondary knowledge is knowledge that we have not specifically evolved to acquire but that has become important for cultural reasons. It is not acquired automatically or unconsciously and is best learned with the assistance of explicit instruction. We invented schools and other educational institutions to teach societally important, biologically secondary, knowledge that otherwise is unlikely to be learned. For example, we can learn to listen and speak without tuition but are unlikely to learn to read and write without explicit instruction. The bulk of the curricula taught in educational institutions fall into the category of biologically secondary knowledge.

Cognitive load theory uses the human cognitive architecture associated with the acquisition of biologically secondary knowledge. Secondary knowledge is processed in a manner analogous to the manner in which biological evolution processes information. The suggestion that evolutionary biology may provide an analog for human cognition has a long history stretching back to Charles Darwin and, more recently, Karl Popper. Both human cognition and biological evolution can be characterized as natural information processing systems.

Principles of Natural Information Processing Systems

There are many ways of describing natural information processing systems. Within a cognitive load theory context, they are most commonly described using five basic principles.

The *information store principle* states that natural information processing systems rely on a very large store of information to enable them to function in a natural environment. A genome provides that role for biological evolution, while long-term memory has an equivalent role in human cognition.

The *borrowing and reorganizing principle* explains how natural information processing systems are able to rapidly acquire their large information stores. During reproduction, information is borrowed from ancestors, with some reorganization of that information during sexual reproduction. Similarly, the bulk of the information stored in human long-term memory is obtained and reorganized by imitating what other people do, listening to what they say, and reading what they write.

While most of the information in an information store is borrowed, it must at some point be created. The *randomness as genesis principle* explains how information is initially created. Random mutation, a process of randomly generating new information and testing its effectiveness, provides the initial creativity engine of evolutionary biology. Analogously, in human cognition, random generation and test during problem solving provide the basic machinery for creativity. No other basic creativity mechanism has been identified.

Random generation has a critical structural consequence indicated by the *narrow limits of change principle*. If novel information must be generated randomly, the system needs a structure to reduce the impact of combinatorial explosions. A very limited-capacity working memory determines which elements will be processed and ensures that humans only process three or four novel elements at any given time. The epigenetic system plays a similar role in evolutionary biology by increasing or decreasing the probability of the relatively rare mutations at particular genetic locations.

Last, the *environmental organizing and linking principle* provides the ultimate justification for a natural information processing system by allowing appropriate actions in specific environments. When dealing with organized information stored in long-term memory, the limitations of working memory disappear, with no known limit to the amount of information from long-term memory that working memory can process. With appropriate information stored in long-term memory in conjunction with environmental triggers, human performance is transformed. Similarly, depending on environmental factors, the epigenetic system can transform the function of the massive store of information held by the genetic system. For example, despite having

identical genetic material, a skin cell has vastly different structural and functional characteristics compared with a liver cell.

Techniques to Reduce Working Memory Load

Cognitive load theory uses this cognitive architecture as a base. The theory is primarily concerned with techniques, some of which are outlined below, to reduce extraneous or unnecessary working memory load in order to facilitate the transfer of information from working to long-term memory for later use.

The *worked example* effect occurs when studying worked examples results in better problem-solving performance than solving the equivalent problems. Searching for a problem solution exerts a heavy extraneous working memory load that contributes little to learning. When learning to solve problems in an area, it is more efficient to have learners study worked examples indicating the solution steps rather than have them attempt to generate solutions themselves.

Eliminating *split attention* can decrease extraneous cognitive load. Imagine a geometric diagram with an associated statement under the diagram: "Angle ABC equals angle XYZ." Learners must split their attention between the diagram and the statement to search for angles ABC and XYZ on the diagram. That search process utilizes scarce working memory resources to mentally integrate the two sources of information. We can eliminate this split attention by placing the statement on the diagram (physical integration) rather than requiring learners to mentally integrate the two sources of information. Physical integration facilitates learning.

Working memory includes partially independent visual and auditory processors. The visual processor deals with two- and three-dimensional visual information, while the auditory processor deals with speech. Using both processors can increase effective working memory capacity, resulting in the *modality* effect. Thus, learning can be facilitated if learners hear "Angle ABC equals angle XYZ" rather than attempting to read the statement while looking at the diagram.

The split-attention and modality effects only apply when two or more sources of information are unintelligible in isolation. In contrast, if, for example, a statement merely redescribes a diagram, it should be eliminated because the presence of both sources of information requires learners to unnecessarily use working memory resources to process the redundant information. Improved learning following the elimination of redundant information provides an example of the *redundancy* effect.

As the levels of expertise in an area increase, the difference between the two instructional techniques may reduce, then disappear, and finally reverse, resulting in the *expertise reversal* effect. In most cases, the effect of redundancy provides the reason for these changes in effectiveness. Information that is required for novices to understand the material may be redundant when provided to more knowledgeable learners.

There are many other cognitive load theory–based instructional effects, with new effects being generated constantly. The ability to generate such effects provides a degree of validity to the theory.

Cognitive Revolution and Information Processing Perspectives

How do people learn, remember, and solve problems? Questions about learning, memory, and cognition have instigated an explosion of empirical research evidence, but building useful answers to these questions requires more than simply assembling a research base. Understanding human learning, memory, and

cognition requires a theoretical framework for systematizing and interpreting existing research and for suggesting new research questions and studies. Influential theoretical frameworks in psychology and education are often conceptualized as metaphors (Sternberg, 1990), and advances in scientific fields can be facilitated by shifts in the conceptual metaphor underlying the dominant theoretical framework of the day (Gardner, 1985; Kuhn, 1970).

In the fields of psychology and education, the *cognitive revolution* refers to the shift from associationist conceptions of how the mind works to information processing conceptions (Mayer, 1992, 1996, 2008a). The *information processing* conception is based on the underlying metaphor of the mind as a computer and has served as the dominant view since the 1960s (Neisser, 1967; Rumelhart, 1977). The goal of this entry is to explore the cognitive revolution, and the information processing view on which it is based, as well as to examine the contributions, limitations, and future of the cognitive revolution.

What Is the Information Processing Perspective?

Humans are processors of information. This statement epitomizes the information processing view of how the human mind works. According to the information processing view, human mental life consists of applying cognitive processes to mental representations. Classic examples include mentally comparing two elements to determine whether they are the same or different, or mentally rotating an image.

Distinction Between Mental Representations and Cognitive Processes

As can be seen, there are two key elements in the information processing view: *mental representations* and *cognitive processes*. Mental representations refer to information or knowledge held within one's information processing system, such as the meaning of this paragraph, or a mental image. Cognitive processes (or mental computations) involve carrying out an operation on a mental representation, such as mentally rotating an image or determining whether two representations are the same or different. A major focus of the information processing approach to how the mind works is specifying how knowledge is represented and manipulated in learning, memory, and cognition.

Mental representations can take a verbal or spatial format, or perhaps some other kind. For example, Figure 1 shows a spatial representation of the first sentence of this section. Developing useful techniques for representing knowledge is a major task of the information processing approach.

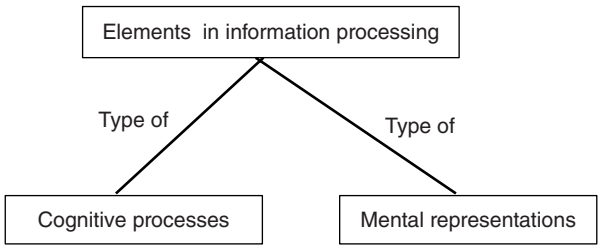

Figure 1 A Mental Representation of Text
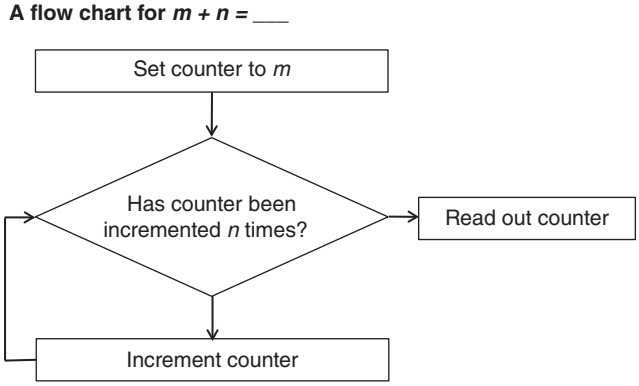
Source: Richard E. Mayer.

Cognitive processes take time and can be described in a flow chart or computer program. Any cognitive task can be broken down into component processes and represented as a flow chart or computer program through a process called *cognitive task analysis*. For example, consider a child who solves the arithmetic problem "What is 2 + 3?" by putting out two fingers on one hand and saying "2" and counting out three fingers one by one in the other hand while saying "3, 4, 5." This is an example of the counting-on procedure for simple addition, which can be broken down into four steps, as represented in the flow chart at the top of Figure 2 and the computer program at the bottom of Figure 2. The first step is to set a counter to the first number (e.g., 2); the second step is to



A program for *m* + *n* = ___

1. Set counter to *m*.
2. Has counter been incremented *n* times?
3. If yes, stop and read out counter.
4. If no, increment counter, and go to Step 2.

Figure 2 Cognitive Processes for Simple Addition
Source: Richard E. Mayer.

determine whether you have incremented it by the second number (e.g., three times), to keep incrementing the counter until you have reached the second number, and then to recite the number in the counter. In this case, cognitive task analysis results in the specification of the cognitive processing involved.

Architecture of the Human Information Processing System

Where do all these mental computations take place? In addition to focusing on mental representations and cognitive processes, a major focus of the information processing approach is on the architecture of the human information processing system, in which memory stores are represented as boxes and cognitive processes are represented as arrows. Figure 3 presents a model of the human information processing system, adapted from Mayer's (2009) cognitive theory of multimedia learning, that consists of three memory stores (sensory memory, working memory, and long-term memory) indicated by boxes, three major cognitive processes (selecting, organizing, and integrating) indicated by arrows, and two channels (visual and verbal) indicated by rows.

Information from the outside world enters the cognitive system through the eyes or ears and is held for a fraction of a second in sensory form in *sensory memory*. If the learner attends to part of the fleeting sensory image (indicated by the *selecting* arrow), some of the information is transferred to *working memory*, where it is represented in a format suitable for applying various cognitive processes (indicated by the *organizing* arrow), which can change the representation. In contrast to sensory memory and long-term memory, working memory is limited in capacity, so that only a few pieces of information can be processed in each channel at any one time. The limited capacity of working memory has crucial implications for how learning, memory, and cognition work, and recognizing the limitations on information processing in working memory is perhaps the single most important contribution of the information processing perspective. The learner can activate relevant prior knowledge from *long-term memory* and combine it with the incoming information in working memory (indicated by the *integrating* arrow). The newly constructed knowledge representation in working memory can be stored in long-term memory, which is the learner's permanent storehouse of knowledge.

Three major principles inherent in the human information processing model shown in Figure 3 are the *dual-channels principle*, the *limited capacity principle*, and the *active processing principle*. The dual-channels principle is the idea that people have separate information processing channels for visual/spatial representations and auditory/verbal representations. The limited capacity principle is that people are able to actively hold and manipulate only a few items in each channel at any one time. The active processing principle is that learning and cognition require active cognitive processing, including selecting relevant information, organizing it into a coherent representation, and integrating it with relevant prior knowledge.

The information processing view is grounded, of course, in a computer metaphor, in which learning, memory, and cognition in computers are likened to learning, memory, and cognition in humans, as summarized in Table 1. The rows represent the three aspects of mental life—learning, memory, and cognition—and the columns show how computers and humans are similar in each of these areas. Overall, both computers and humans receive information from the outside world, store it in memory, and perform operations on it.

Table 1 How Is a Computer Like a Human?

Domain	*Computers*	*Humans*
Learning	Information is input into computers.	Information is presented to humans.
Memory	Computers store information in memory and retrieve information from memory.	Humans store information in memory and retrieve information from memory.
Cognition	Computers perform computations on the stored information.	Humans apply cognitive processes to mental representations.

Two Versions of the Information Processing Perspective

The fundamental elements in the information processing approach are the distinction between the concept of information (i.e., mental representations) and the concept of processing (i.e., cognitive processing), but researchers can differ in how they conceptualize this. Thus, although the information processing perspective can take different forms, most information processing models can be classified as the classic view or the constructivist view, based on how they conceptualize the nature of mental representations and the nature of cognitive processing.

As shown in the top row of Table 2, in the classic view, human cognition consists of applying operations to information. As proposed in information theory, information is an objective commodity that exists in the same form in the outside world as in someone's mind. For example, knowing whether a digit is a 0 or 1 provides the same piece of information whether it is represented on a piece of paper, in a computer's memory, or in a human's memory.

Table 2 Two Versions of the Information Processing View

Version	*Mental Representations*	*Cognitive Processing*
Classic view	Information	Applying operations
Constructivist view	Knowledge	Selecting, organizing, and integrating knowledge

As proposed in computer simulation models, an operation is a precise algorithm (or procedure) that for any given input will always give the same output. For example, using arithmetic operations, inputting 2 + 3 always gives you 5 as the output. The classic view can be commended for its precision, but it can be criticized on the grounds that it reduces human cognition to symbol manipulation.

In contrast, as shown in the bottom half of Table 2, in the constructivist view people engage in knowledge construction by selecting important pieces of incoming sensory information, mentally organizing them into coherent mental representations, and integrating them with relevant prior knowledge. In short, learning, remembering, and thinking are sense-making activities in which a new cognitive structure is created. In the constructivist view, mental representations are knowledge structures that are constructed by the learner rather than transmitted from the environment, and cognitive processing involves activity aimed at building knowledge structures, such as selecting, organizing, and integrating. The constructivist view can be criticized for its lack of precision and commended on the grounds that it restores human cognition to a sense-making activity, consistent with earlier musings by Bartlett (1932), Piaget (1971), and the Gestalt psychologists. An important goal of cognitive science has been to meld an approach that has the theoretical authenticity of the constructivist view and the methodological precision of the classic view.

What Is the Cognitive Revolution?

Table 3 summarizes three visions of how the mind works for learning and remembering—*response strengthening*, *information acquisition*, and *knowledge construction*. When scientific psychology began in the late 1800s, the dominant view of how the human mind works was borrowed from a 2,000-year-old tradition of associationist theory in mental philosophy. According to this view, labeled as "Response strengthening" in the top row of the table, learning involves strengthening and weakening of stimulus–response associations, based on the consequences of the learner's actions. According to this view, remembering involves following a chain of associations from the stimulus to the most strongly associated response. Although the response strengthening view dominated psychology for the first half of

Table 3 Three Visions of Learning and Remembering

View	*How Learning Works*	*How Remembering Works*
Response strengthening	Strengthening or weakening associations	Following a chain of associations
Information acquisition	Adding information to memory	Retrieving information from memory
Knowledge construction	Building cognitive structures	Reconstructing cognitive structures

the 20th century, boosted in part by its methodological precision and affordances for mathematizing human cognition, it has been criticized for difficulties in explaining how people create novel solutions to problems they have not seen before and for its focus on rats and pigeons rather than humans.

The cognitive revolution in the 1950s and 1960s propelled a competing view to prominence based on the challenges of explaining how humans learn rather than how lab animals learn—the information acquisition view. As shown in the second row of the table, according to the information acquisition view, learning involves putting information into memory, and remembering involves taking it out. By the 1970s and 1980s, a modified version came to prominence; it was based on the challenges of explaining how the mind works in authentic contexts rather than on contrived laboratory tasks—the knowledge construction view. As shown in the third row of the table, learning involves building mental representations by integrating incoming information with existing knowledge rather than building up the strength of memory traces. In addition, remembering involves reconstructing one's knowledge rather than simply plucking a memory trace from memory.

An emerging modification is the social constructivist view, which holds that knowledge construction can be influenced by the social context in which it occurs, such as through discussion. This mild version of social constructivism can be seen as an extension of the third row in the table.

The Crucial Work in the Late 1950s

The year 1956 is often listed (sometimes along with 1957) as the turning point for the cognitive revolution, as reflected in the convergence of several important publications: Miller's (1956) "magical number seven" review of performance on classic lab tasks, showing that humans consistently displayed a limited capacity for cognitive processing in what is now called working memory (which seemed to be able to hold in attention seven chunks of information, plus or minus two chunks); Bruner, Goodnow, and Austin's *A Study of Thinking* (1956), showing that unlike lab animals, which appear to strengthen and weaken responses in discrimination learning tasks, humans tend to construct and test hypotheses in concept learning tasks; Chomsky's *Syntactic Structures* (1957), showing that the field of linguistics could be improved by considering how language utterances are represented in the learner's mind (as deep structure) rather than simply based on formal syntactic rules (as surface structure); and the first influential computer simulation of complex thinking reported by Newell and Simon (1956).

Although the 1950s marked the beginning of the cognitive revolution, there were earlier musings about an alternative to the idea that the mind mainly involves the strengthening and weakening of associations. Bartlett (1932) offered a cognitive view by demonstrating that people interpret stories to fit with their existing schemas both at the time of learning and at the time of remembering. Similarly, Piaget (1971) demonstrated how children's learning and development can be viewed as assimilating incoming information to existing schemas (or accommodating it by constructing new ones), rather than as building associations. Gestalt psychologists and their forerunners showed that creative problem solving involves building cognitive structures rather than following a chain of responses.

The Cognitive Revolution in Applying the Science of Learning to Education

The cognitive revolution can be seen as an attempt to address practical problems (e.g., the educational question of how to help students learn to read, write, or do arithmetic) and theoretical problems (e.g., how learning works). Stokes (1997) uses the term *use-inspired basic research* to characterize research that has both theoretical and practical implications, in contrast with pure basic research (with no practical goal) or pure applied research (with no theoretical goal). In attempting to apply the science of learning to educational problems, the cognitive revolution is shaped by the dual goals of building a science

of instruction (i.e., in response to practical problems in the real world) and building a science of learning (i.e., by extending learning theory to account for authentic learning situations). In short, practical problems helped create the cognitive revolution by challenging psychologists to explain learning, memory, and cognition beyond the confines of contrived lab tasks.

Reciprocally, the cognitive revolution contributed to solving practical problems in education by helping spawn psychologies of subject matter, such as in reading, writing, and arithmetic. In reading, for example, cognitive research shows that learning to read printed text depends on students being able to engage in the cognitive processes of detecting and producing each of the sound units of their language—which has been called *phonological awareness*. In writing, cognitive research shows that proficiency in writing essays depends on students being able to engage in the cognitive process of generating and organizing ideas—which has been called *planning*. In arithmetic, cognitive research shows that learning to add and subtract depends on students being able to conceptualize and manipulate a *mental number line*. In short, cognitive research helped identify phonological awareness as a readiness skill for learning to read, planning as a readiness skill for writing, and the mental number line as a readiness skill for arithmetic.

Contributions of the Cognitive Revolution

The following are some contributions of the cognitive revolution and the information processing view it instigated.

1. The cognitive revolution involved a move away from a focus on behavior to a focus on the mind and from associationist conceptions of how the mind works to an information processing view. Humans are viewed as active processors of information rather than passive recipients of rewards and punishments.
2. The cognitive revolution instigated a unified and powerful framework for explaining learning, memory, and cognition, based on flow chart models with memory stores as boxes and cognitive processes as arrows. A particularly important aspect of the information processing model is that working memory is limited in capacity—a conception that has crucial implications for learning, memory, and cognition.
3. The cognitive revolution created a lasting change that has undergone several important adjustments in the course of the past 50 years, including a constructivist conception of how information processing works. This long-lasting conception has stimulated useful research in the field.
4. The cognitive revolution highlighted the role of mental representations and cognitive processing in mental life, and led to clearer descriptions of the role of knowledge and processes in the performance of cognitive tasks.
5. The cognitive revolution highlighted the role of cognitive processing in mental life and, as with mental representations, led to clearer descriptions of the role of knowledge processes in the performance of cognitive tasks.
6. Finally, the cognitive revolution fostered a transition from research on lab animals to research on humans and, eventually, from research with contrived lab tasks to research on authentic tasks.

Limitations of the Cognitive Revolution

Some of the limitations of the cognitive revolution are the following:

1. The cognitive revolution did not explicitly consider the role of affect, interest, and motivation or the role of social, cultural, and evolutionary factors. By focusing solely on cold cognition, the information processing model was incomplete.
2. The cognitive revolution did not initially take advantage of research in neuroscience, but current work in cognitive neuroscience is addressing this shortcoming.
3. The cognitive revolution did not adequately address the role of executive control in the information processing system, such as metacognitive awareness and control of the information processing system.
4. The cognitive revolution initially viewed mental representations as objective information rather than as constructed knowledge.
5. The cognitive revolution initially viewed cognitive processing as applying algorithms rather than as constructing knowledge.
6. The cognitive revolution initially focused on contrived laboratory tasks rather than on authentic, real-world tasks.

However, as the information processing approach has matured, progress has been made in overcoming each of these shortcomings.

What Is the Future of the Cognitive Revolution?

The cognitive revolution and the model of information processing it inspired represent an important step in creating an alternative to associationist conceptions of how the mind works. Born in the 1950s and in the 1960s, the information processing model has proved to be a remarkably useful, resilient, and adaptive intellectual force in psychology. This resiliency can be seen in the way the information processing model has morphed from the classic view (in which information is manipulated) to the constructivist view (in which knowledge is constructed), in response to challenges to explain learning and cognition in authentic situations, or what can be called "applying the science of learning." The resiliency can be attributed to the way the information processing approach offers a general framework (or language about cognitive processing) into which current theories can easily fit.

What does the future hold for the cognitive revolution and its information processing perspective? The information processing perspective is challenged on the left by radical social constructivism, on the right by cognitive neuroscience and computational modeling, and from the past by the unfinished business of Gestalt psychology.

Challenges From Radical Social Constructivism

First, the cognitive revolution faces challenges on the left from radical social constructivism, which holds that knowledge is stored and processed solely in social groups rather than in individual minds. Instead of enriching or extending the information processing model, radical constructivism calls for its complete elimination along with cognitive science. Although there is some empirical evidence for the mild version of social constructivism (which holds that people working together can help each other learn and solve problems), there is little empirical or logical support for the radical version (which, like the behaviorists of yesteryear, banishes cognitive processing from human minds).

Challenges From Reductionism

Second, the cognitive revolution faces challenges on the right from the forces of reductionism—in the guise of replacing psychology with either neuroscience or mathematics, or perhaps both. Although cognitive neuroscience has potential to help test and refine the information processing model in ways not available through purely behavioral research, the cognitive revolution is threatened by attempts to replace the mind with the brain, replace cognitive processes with ERP (event-related potential) patterns, and replace knowledge structures with fMRI (functional magnetic resonance imaging) images. Throughout its more than 100-year existence, psychology has faced the constant threat of being reduced to biology. Although understanding how the human mind works can be informed by biology, it should not be replaced by it.

Similarly, the history of the cognitive revolution is replete with attempts to mathematize human mental life, sometimes as equations (Hull, 1943) and sometimes as computer programs (Newell & Simon, 1972). However, although equations and computer programs can be helpful in clearly rendering various cognitive theories, they are tools for representing theories about information processing rather than the theories themselves.

Challenges of Unfinished Business

Finally, the constructivist version of the information processing view, which currently is the dominant view, has its roots in the classic vision of learning and cognition as structure building. The structure building notion is reflected in Bartlett's (1932) vision of learning as assimilation to schema, Piaget's (1971) notion of cognitive development as assimilation and accommodation of schemas, and Gestalt notions of perception and cognition as mentally reorganizing elements into a coherent structure. In some ways, today's vision of human mental life as consisting of structure building—that is, constructing schemas—represents a return to the unfinished business of Gestalt psychology. In short, the information processing approach is poised to address the enduring challenge of understanding the cognitive processing involved in building cognitive structures, which underpin human understanding.

In a stinging critique of Gestalt approaches to mental life written nearly 60 years ago, Estes (1954) asked why it is that, if Gestalt theories based on understanding and meaning and organization are so superior, "the most superior theories of learning have had the least influence upon research" (p. 341). Estes's critique still has the ring of truth

today, because over the years, research based on the classic version of information processing has yielded a much larger research base than research based on the constructivist version of information processing. Yet as the information processing approach continues to develop in the 21st century, it may finally prompt the rigorous and innovative research needed to better understand the role of structure building in learning and cognition.

Coleman Report

On July 2, 1966, the U.S. Commissioner of Education, Harold Howe II, submitted to the president and the Congress a national report, Equality of Educational Opportunity, usually referred to as the Coleman Report after its lead researcher, the Johns Hopkins University sociologist James S. Coleman. The report was a response to a congressional mandate in Section 402 of the Civil Rights Act of 1964:

> The Commissioner shall conduct a survey and make a report to the President and the Congress, within two years of the enactment of this title, concerning

> the lack of availability of equal educational opportunities for individuals by reason of race, color, religion, or national origin in public educational institutions at all levels in the United States, its territories and possessions, and the District of Columbia.

This entry discusses how the national survey that led to the findings was conducted, why the report was considered groundbreaking, the findings of the report, and its ongoing legacy.

Coleman assumed primary responsibility for survey design and data analysis for the project overall; the report was commonly referred to as the Coleman Report. The survey was collected by Ernest Campbell at Vanderbilt University. Campbell played a key role in conducting the surveys in higher education. The survey team study also received advice from an 18-member national advisory committee made up of six urban school superintendents, two presidents of historically Black institutions of higher education, and one state education commissioner.

The national survey, which had an overall response rate of about 70%, was a major undertaking even by today's standard. Data were collected during September and October 1965. The sample included about 60,000 teachers and administrators as well as 600,000 students in 1st, 3rd, 6th, 9th, and 12th grades in more than 3,000 schools across the nation. Survey response was somewhat uneven across regions, with about 60% and 80% of nonurban schools in the South and the North participating, respectively.

The Coleman Report marked the beginning of a new era for social science research in addressing key societal concerns. Coleman went beyond simply providing descriptive statistics by applying statistical methods for inferences. As high-speed computers became more readily available to the social science community in the mid-1960s, Coleman and his associates were able to make use of the advantages of surveys with large sample sizes and multiple variables at multiple levels of the school organization. In reviewing Coleman's contributions to the study of education issues, James Heckman and Derek Neal observed that the research of the Coleman Report "demonstrated the value of large-scale data sets and empirical social science for evaluating social programs" (Heckman & Neal, 1996, p. 84).

The Coleman Report offered a systematic look at the status of equality of opportunity in public education in the mid-1960s. The data collection focused on six racial and ethnic groups. These groups, using the social categories in 1965, were Negroes, American Indians, Oriental Americans, Puerto Ricans living in the continental United States, Mexican Americans, and Whites.

The report found that public education was racially segregated. In the South, the report found that "most students attended schools that are 100 percent white or Negro." In 1965, 54% of the Black school-age population lived in the South. At the national level, about two thirds of all Black students attended schools that were racially isolated, with Black students making up at least 90% of the student body. Eight out of 10 White students were enrolled in racially isolated schools with at least 90% White students.

Using disaggregated data across different racial and ethnic groups, the survey showed a significant and persistent majority–minority achievement gap over the course of schooling. At the first grade, minority students on average scored at one standard deviation below their White peers. This initial achievement gap, however, worsened as the grade progressed. For example, while Black sixth graders were 1.6 years behind their White peers in achievement, the former was 3.3 years behind the latter at 12th grade.

The Coleman Report was groundbreaking not only because of its extensive treatment on an important societal challenge but also because of its empirical examination of the relationship between school-based resources and student achievement. In this regard, the report challenged the conventional understanding of a straightforward, positive relationship between school resources and student achievement. In a 1983 interview, Coleman reflected on the different approach:

> Ordinarily, quality of schools had been defined in terms of inputs to the schools. We asked about outputs, using achievement outputs as criteria for judging the relative quality of schools. Even though that was not exactly a result, I think it had an important effect in reshaping the way in which educational research questions were asked after EEOC [Equality of Educational Opportunity]. (quoted in Barber, 1987, p. 34)

Although the report's analytical design and methods have been scrutinized by succeeding generations of policy analysts and social scientists, the main research questions posed by Coleman and his

associates on the relationship between inputs and outputs remain relevant. The report offered an empirical approach to measure the types of inputs that were assumed to affect schooling outputs. In this regard, key findings of the Coleman Report would influence how policy analysts and policymakers think about the nature of equal educational opportunities.

Coleman and his associates found that school resources, including school facilities, curriculum, and teacher quality, did not show overall statistically significant effects on student achievement. According to the report,

> Differences in school facilities and curriculum, which are the major variables by which attempts are made to improve schools, are so little related to differences in achievement levels of students that, with few exceptions their effects fail to appear even in a survey of this magnitude.

School resources, however, were found to have some positive effects on student achievement for Black students. Variations in teacher quality were found to have a cumulative effect on student achievement over the years, and these effects were greater for racial minorities than for White students. Teachers' verbal scores and educational backgrounds, for example, had a positive effect on achievement for minority students in the upper grades. For the whole student sample, including White and minority students, there was a general lack of significant effects of teacher characteristics, as measured in terms of teacher quality, teachers' family education level, teachers' own education, and teachers' score on a vocabulary test.

Variations in school facilities, including science laboratories, showed positive effects on Black student achievement. Resource variations did not generate significant effects for White students. As the report stated, "It is for majority whites that the variations make the least difference; for minorities, they make somewhat more difference." In other words, resources seemed to have differential effects on different racial groups.

The Coleman Report also made another important contribution by showing the differential effects of racial backgrounds on student achievement. The report found a strong relationship between the social composition of schools and student academic achievement. As the report observed, "Attributes of other students account for far more variation in the achievement of minority group children than do any attributes of school facilities and slightly more than do attributes of staff." The report further clarified that higher student achievement was associated with a more diverse student body that encompassed diverse educational backgrounds and aspirations. As the report explained,

> The higher achievement of all racial and ethnic groups in schools with greater proportions of white students is largely, perhaps wholly, related to effects associated with the student body's educational background and aspirations. This means that the apparent beneficial effect of a student body with a high proportion of white students comes not from racial composition per se, but from the better educational background and higher educational aspirations that are, on the average[,] found among white students.

This second major finding on social composition has played an important role in forming the empirical basis for those who advocated for racial integration in public schools.

Since its publication almost 50 years ago, the Coleman Report has generated broad interest and debate on the effects of schools and families on student achievement. Generations of scholars in sociology of education and education policy have debated the report's scholarly and policy impact. The report's findings have inspired doctoral dissertations, foundation grants, and governmental intervention. Many studies, with growingly sophisticated research design over time, have questioned whether the Coleman Report has underestimated the effects of schooling conditions on student achievement, whether the sampling procedures were properly handled, whether the implications on racial integration were exaggerated, and whether the survey response rate was sufficient, among other concerns. At the same time, many more studies continued to recognize the groundbreaking contributions of the report on understanding equal opportunities in public schools. Clearly, the work of the Coleman Report remains just as relevant today in our growingly diverse society as it was half a century ago.

Colonialism and Postcolonial Theory

In its current form, postcolonial theory has emerged out of what has been called the "cultural turn" in the social sciences, although the term *postcolonial* itself has a longer history. It was widely used by historians after World War II to designate the postindependence period. In this sense, postcolonialism has a chronological meaning, referring to national formations after the colonial period had formally ended. Since the 1970s, however, postcolonial theory has involved debates over the manner in which colonial experiences are represented and about the ways in which European colonization has left residual and persistent effects on both the colonized and colonizing people. Located largely in the disciplines of literary and cultural studies, recent postcolonial theory has been used to interrogate the discursive origins of colonial rule, drawing on a longer tradition of critical, anticolonial theorizing, on the one hand, and on newer poststructuralist resources of philosophizing, on the other. In this way, postcolonialism has demanded a rethinking of knowledge and social identities authored and authorized by colonialism. Applied to education, postcolonial theory emphasizes the importance of understanding the link between globalization and education—namely, that educational policies and practices are always to be understood in terms of the historical legacy and the emerging cultural forces specific to a given locale.

Theoretically, postcolonialism draws attention to the ways in which language works in institutionalizing various colonial relations of power. It is thus based on a theory of meaning that views language in terms of its performance functions, assuming discourse and power to be inextricably linked. This does not imply there is nothing "outside the text," as some strands of thinking in poststructuralism appear to suggest. Rather, postcolonialism points to the ways in which social texts are shaped by a range of economic and political forces and interests at various levels of practice. Postcolonialism's aspirations are thus not only theoretical but also political. Postcolonial analysis seeks an understanding, for example, of the manner in which global inequalities are perpetuated both through the distribution of resources and through neocolonial modes of representation. In political terms, such an analysis, it is argued, has the potential to suggest ways of resisting colonial power in order to forge a more socially just world order. Rather ambitiously, Robert Young argues that "postcolonialism seeks to change the way people think, the way they behave, to produce a more just and equitable relation between different peoples of the world" (Young, 2003, p. 7).

Colonial Discourse: The Influence of Edward Said

Although the historical origins of postcolonial theory are contested, Edward Said is often cited as a central figure in its development. In his book *Orientalism* (1979), Said uses the Foucauldian insights concerning the nexus between knowledge and power to provide a theoretical account of how knowledge about the "Orient" was produced and circulated as an ideological accessory to colonial power—that is, how European representations of non-European cultures were used as instruments of power and how many of these representations continue to inform contemporary economic, political, and social practices. Said uses the notion of discourse to reconceptualize the study of colonialism. He shows how representations of the "Orient" in European literary texts, travelogues, and other writings contributed to the creation of a binary between Europe and its "others" and how colonial discourse has been fundamental to the maintenance and extension of European hegemony over other lands, through a range of normalizing

assumptions about European superiority over the groups of people Europe colonized.

It is important to note that *colonial discourse* is not simply a new term for colonialism. Rather, it suggests a new way of thinking about how economic, cultural, political, and educational processes work together in both the creation and the perpetuation of colonialism, on the one hand, and in the organization of resistance to it, on the other. The scope of the studies of colonial processes is thus widened to include an interrogation of the intersection of ideas and institutions, and knowledge and power. As Ania Loomba (1998) points out, colonial violence can now be understood as including an "epistemic" dimension—an attack on the ideas, values, and cultural institutions of the colonized peoples (p. 54). A postcolonial examination of colonial discourse thus requires an assessment of how stereotypes, images, and various cultural generalizations are linked to the institutions of economic, judicial, and administrative control, including control exercised through schools, colleges, and universities.

A significant body of literature now exists that demonstrates the ways in which such generalizations are shaped by colonial assumptions. For example, in most colonial texts, Europe is represented as the place of historical progress and scientific development, while colonized cultures are deemed to be remote from enlightened historical shifts. From the perspective of European norms, colonized cultures are assumed to be peculiar—unusual, fantastic, and bizarre. Ultimately, these portrayals serve as markers of Oriental inferiority, while the West is assumed to be sensible, rational, and familiar. Non-European cultures are moreover represented in terms of various invidious racial stereotypes, such as the violent Arabs, lazy Indians, and inscrutable Chinese. The colonial discourse also involves popular stereotypes of the effeminate Oriental male and the sexually promiscuous Oriental female.

Responses to Said: Bhabha and Spivak

As influential as Said's discussion of the nature of colonial discourse has been, it has evoked a whole range of critical responses and elaborations. A number of subsequent theorists have been critical of the universalizing tendencies in Said's account of Orientalism. According to Homi Bhabha (1994), for example, colonial discourses are often more ambivalent, and much less resolute, than is implied in Said's analysis. Bhabha refuses to interpret identity and difference in essentialist terms, conceptualizing them instead in terms of the overlapping, migratory movements of cultural formations across a global division of labor. He highlights the "in-between" categories of competing cultural differences and suggests that postcoloniality always involves the "liminal" negotiation of cultural identity across differences of race, class, gender, and cultural traditions. He argues that cultural identities cannot be ascribed pregiven, irreducible, scripted, and ahistorical cultural traits. Nor can the "colonizer" and the "colonized" be viewed as separate entities that define in terms that are independent of each other.

For Bhabha (1994), identity is always "hybrid," produced performatively in contexts that are sometimes antagonistic and sometimes affiliative. He maintains that "the social articulation of difference, from the minority perspective, is a complex, ongoing negotiation that seeks to authorize cultural hybridities that emerge in moments of historical transformation" (p. 23). Bhabha thus refuses to view colonial power in an absolute sense, always guaranteed to produce the intended effects in the colonial subjects. Instead, he believes that it involves subversion, transgressions, insurgence, and mimicry.

In this way, Bhabha accords considerable importance to the colonized subject's linguistic agency.

The question of the extent to which it is possible for colonial subjects to enact this agency is central to the work of Gayatri Spivak (1988). She argues that the capacity of the colonized subject to resist may itself be constrained by the linguistic power of the dominant group, along with the incapacity of the powerful to hear the voice of the subaltern. She cautions against the claim that it is always possible for the postcolonial historian to recover the voice of the subaltern, suggesting that this assumption underestimates the repressive scope of colonial hegemony and, especially, of the ways in which it has historically intersected with patriarchy. Spivak does not, however, entirely dismiss the desire of postcolonial intellectuals to highlight the nature and scope of the colonial oppression from the perspective of the marginalized people. Instead, she underscores the dual perspective embodied in Antonio Gramsci's description of himself as a pessimist because of intelligence, an optimist because of will.

For Bhabha, this politics is best captured by the notion of hybridity. It is in its hybrid forms that colonial knowledge can be reinscribed and given new, unexpected, and oppositional meanings, as a way of "restaging the past." This emphasis on

hybridization demolishes forever the idea of subjectivity as stable, single, and pure, drawing attention instead to the ways in which subjugated people can challenge exclusionary systems of meaning and thus disrupt the exclusionary binary logics on which discourses of colonialism, nationalism, and patriarchy depend. It is this insight that has inspired much of the recent works in postcolonial history, literature, and the arts, seeking ways to interrupt and challenge colonial ways of thinking about the world.

However, in these works, hybridity is often valorized. While it is true that the postcolonial condition is underlined by much variability; multivocality; and the processes of fuzziness, cut and mix, crisscross, and crossovers, suggested by the idea of hybridity, it is also the case that the processes of cultural hybridization are never neutral but involve a politics expressing issues of economic and cultural power. A celebration of syncretism and hybridity always runs the risk of obscuring the scope of colonial violence, unless it is articulated along with a critical focus on the issues of hegemony and neocolonial power relations. So while, as a theoretical idea, hybridity is a useful antidote to cultural essentialism, it cannot in itself provide the answers to the difficult questions of how hybridity takes place, the form it takes in a particular context, the consequences it has for particular cultural groups, and when and how particular hybrid formations are progressive or regressive.

Broader Critiques of Postcolonial Theory

Broader criticisms of postcolonial theory relate to the ways in which it privileges discourse over "concrete" phenomena such as economic and social conditions that remain the major sources of oppression and marginalization. Dirlik (1994) has pointed out, for example, that Said, Bhabha, and Spivak draw too heavily on Western poststructuralist thought, which has conceded too much ground by questioning oppositional discourses such as nationalism and Marxism, precisely at a time when such discourses are most needed to combat conflicts around the world. Other critics have objected to the impression that postcolonial theory appears to give an end to colonialism, instead of focusing on its more contemporary forms. According to Ahmad (1995), "Speaking with virtually mindless pleasure of transnational cultural hybridity, and of politics of contingency, amounts in effect, to endorsing the cultural claims of the transnational capital itself" (p. 12). Ahmad thus accuses postcolonial theory of being complicit with global capitalism, since its focus on discourse masks the question of the ways in which capitalism continues to use racial differentiations to pursue its objectives.

Achievements of Postcolonial Theory

While some of these criticisms of postcolonial theory clearly have merit, postcolonialism's achievements cannot be denied. Perhaps its key achievement is the insistence on the cultural dimensions of colonialism. It has shown that far from being secondary to economic formations, culture must be viewed as essential to the production and maintenance of colonial relations. It has suggested how new analytical strategies are needed for understanding both economic and cultural politics of colonialism without reducing one to another. Without such strategies, it may not be possible to understand how contemporary social conditions, such as those characterized by globalization, for example, demand reference to the continuities and discontinuities of colonialism.

Postcolonial theory has the potential to help us understand how the persistence of global inequalities, and the threats to the continued existence of local cultures and traditions by the global consumerist culture, is anchored in the traditions of Western colonialism. New information and communication technologies have enabled instantaneous circulation of information, ideas, and images, making it possible to conceive of the world as a single space shared by all of humanity. However, the routes of this circulation are seldom symmetrical and equal. They are shaped by the history of colonial discourses. Postcolonial theory raises the question of the extent to which the so-called global culture has reproduced the colonial patterns of inequalities.

Another major achievement of postcolonial theory has been the account of the dialectical relationship between the colonizers and the colonized. It has shown how the colonizers not only shape the cultural representations of the colonized but are also, in turn, shaped by colonialism in a range of complex ways. Nor can the colonized be regarded simply as innocent bystanders in their encounters with the hegemonic processes of colonization. Postcolonialism refuses to treat the colonized as "cultural dupes," incapable of interpreting, accommodating, and resisting dominant discourses. And so it is with contemporary global relations, which necessarily involve negotiation of cultural messages, even if this occurs in spaces that are characterized by asymmetrical power relations. Postcolonial theory

points to the inherent dangers in the analyses of contemporary cultural practices, which are overdetermined by global capitalism and regard globalization as historically inevitable.

Postcolonial theory is helpful in understanding contemporary educational formations in a range of ways—for example, in articulating the relationship between globalization and education. Postcolonialism stresses the need to avoid the universalistic impulse at the core of many conceptions of this relationship. If most education occurs at the local level, then, it suggests that local practices are connected to historical legacies as well as emerging cultural forces. However, these forces do not simply exist in some abstract fashion to simply be "read off" for their implications for educational policy and governance. They need to be understood historically and relationally. It is only through this kind of complex understanding that it is possible to recognize new modes of colonial power and to devise ways of resisting them.

Comenius, Johann Amos

Johann Amos Comenius (in Czech, Jan Amos Komensky; 1592–1670) is among the most influential figures in the history of education. He lived during a century when revolutionary changes were taking place in Europe: on the one hand, a series of highly destructive wars (the "Thirty Years' War"), which basically changed the political balance, impoverished large areas for decades, and deepened the schism between religious denominations, and, on the other hand, the emergence of the modern world—the territorial state, the mercantilist economy and industrial production, and the modern sciences.

Comenius was raised in the community of the Bohemian Brethren, a Protestant movement within the Catholic Habsburg territories of Bohemia and Moravia, now incorporated into the modern Czech Republic. He studied theology, served as a minister and schoolteacher, and later on became bishop of the Brethren. Beyond that, he was highly engaged in realizing a vision of peace, unity, and order in a world that he perceived as a chaotic labyrinth—as he described it in his *Labyrint světa a ráj srdce* (*Labyrinth of the World and Paradise of the Heart*, 1631). In his magnum opus, *De rerum humanarum emendatione consultatio catholica* (*General Consultation on an Improvement of All Things Human,* 1666), he worked out a way to heal the sufferings of the world. At the center of this work, Comenius deals with efforts to create order in all things that are totally disordered (*pansophia*), in all thinking that is entirely confused (*panpaedia*, meaning "universal education"), and in all the languages that are totally discordant (*panglottia*). This structure corresponds strictly to Comenius's pivotal concern, namely, education and languages. Comenius's *Weltbild* (concept of the world), and thus his theology and his philosophy, was grounded in the tradition of the community of the Brethren and in the universal scientific discourse of his time. He tried to bring things together: to work out a *pansophia*, an ordered encyclopedia of all that mankind knows and has experienced and which is based on a Christian concept of the world.

Comenius was the first to successfully organize all the available knowledge that humankind had accumulated and to turn it to the didactic purpose indicated in the title of his famous *Didactica Magna* (*Great Didactic*). His famous textbook the *Orbis Sensualium Pictus*, a language-picture textbook, is a telling example of this and one of the classics of education. In this book, the world, the circle (*orbis*) of Creation, is expressed symbolically in words and pictures, with the words explaining the pictures and vice versa. Thus, the world becomes teachable.

Looking back on his life, and to the miserable state of the church and the schools in his mother country, Comenius wrote in 1657, "Before all we should help the youth and establish schools as soon as possible, and provide them with appropriate textbooks and a precise teaching method in order to put their academic, moral, and religious efforts on the right path." So in his *Great Didactic* (setting forth the whole art of teaching all things to all men), he outlined a vision of a comprehensive school system. In Greek and Latin, Comenius plays on a little word: *pan*—omnis—*all*, that comprises philosophy in its entirety and his vision of education in particular.

In the *Great Didactic*, Comenius (1657/1907) argues in a way that is representative of his pedagogical argument:

> Artisans are accustomed to fix certain limits of time for the training of an apprentice . . . , according to the case or difficulty of the trade. . . . The same system must be adopted in school organisation, and distinct periods of time must be mapped out for the acquirement of arts, sciences, and languages respectively. In this way we may cover the whole range of human knowledge within a certain number of years. . . . The process should begin in infancy and should continue until the age of manhood is reached; and this space of twenty-four years should be divided into well-defined spaces. In this we must follow the lead of nature.

Artisans, nature, and—if helpful—the Bible are referenced in all of Comenius's arguments. The latter source is, of course, traditional; the former indicate the influence of emerging modern philosophy and sciences. For Comenius, these references are closely linked as there is one and the same logic behind them: the theologic of God's creation and the destiny of the world.

In his time, Comenius's name as educator stood for his language textbooks. Nowadays, one can interpret those famous books as part of a tripartite unity of a sequence of

- comprehensive schools, one building on another according to the students' age, with
- corresponding textbooks that present the entire world according to the order of God's creation, and
- books that guide a teacher in how to introduce youths into the world they occupy, a *didactic*.

The System of Schools (*Omnes*—for All)

According to Comenius, the school system looks like this: "The whole . . . must be divided into four distinct grades: infancy, childhood, boyhood [*sic*], and youth." The schools should be *the mother's knee*, *the vernacular school* (our elementary school), *the Latin school or gymnasium*, and *the university and travel*—in every house, every village, every city, and every kingdom, respectively. This picture mirrors the schools of the 17th century in Europe. Comenius put things together into a system of comprehensive schools for all, which is theoretically consistent. This vision was far from being realized in his time; but the idea has encouraged educational reformers down to the present, particularly in countries with noncomprehensive school systems.

The Knowledge (*Omnia*—All Things)

In his lifetime, Comenius was famous for his textbooks or, more precisely, for his language books. Above all, his *Janua linguarum reserata* (*The Open[ed] Door to the Languages*) established his fame. The book's pattern has been well known through the centuries. In this textbook, as well as in all the others, the world is represented symbolically by means of languages, Latin being the lingua franca. (In particular, Comenius rendered outstanding services to the Czech language, his mother tongue.)

Comenius's idea was to elaborate one appropriate textbook for each of the types of school that he had outlined. The best known, even in our own day, is the *Orbis Sensualium Pictus* (*The World in So Far as We Can Conceive It With Our Senses*). This textbook was designed for the *mother school*, the school "for infancy that should be the mother's knee." In this book, Comenius represents the entire circle of the world, the *orbis*, in words and in pictures. A closer look into this primer discloses Comenius's didactic philosophy: First of all, his textbooks are more than mere dictionaries; rather, they tell stories about the world as it reveals itself to the human senses. These stories are about nature and human life, and they are embedded in a concept of what use to make of things and how to act humanely in human society. The introduction to his *Unum Necessarium* (*The One Thing Needful*) gives the principle of selection, composition, and presentation of things in all of his language-matter books—all "what every human really needs for this transitory life, under the guidance of sane senses and the word of God."

A second point to be made is that the manifold of human knowledge is ordered according to the lives of humans in this world, which prepares them for their eternal life. The *Orbis Pictus* is intended to be a persuasive demonstration of Comenius's basic philosophy, and it is therefore a key to the understanding of the bulk of his didactic writings:

- Its title could also be translated as "The *world as God's creation* in pictures."
- The content itself is framed according to a Christian *Weltbild:* The book begins with God and His Creation; the last picture is the Last Judgment.
- The entire matter in turn is explicitly framed didactically through an invitation ("Come boy, learn to be wise") and a *clausula* (conclusion: "Thus thou hast seen in short, all things, that can be shown, and hast learned the chief Words of the English [German, Czech etc.] and Latin Tongue. Go on now and read other good Books diligently, and thou shalt become learned, wise, and godly"). Furthermore, the corresponding pictures are identical, a fine example of the pictures' message.

The Method (*Omnino*—Throughout)

In the course of developing his didactic, Comenius first of all refers to the Bible and to the ancient philosophers and theologians. This way of arguing was an age-old practice and a sort of legitimation of his argument by recourse to generally accepted authorities. But when it came to the substance of his teachings, he followed the philosophical reasoning of his time—that of the emerging philosophy of the Enlightenment. In the words of René Descartes (with whom Comenius occasionally visited),

> I perceived it to be possible to arrive at knowledge highly useful in life; and . . . to discover a practical [philosophy], by means of which, knowing the force and action of fire, water, air, the stars, the heavens, . . . as distinctly as we know the various crafts of our artisans, we might also apply them in the same way to all the uses to which they are adapted, and thus render ourselves the lords and possessors of nature. (*Discourse on Method*, Part VI)

In this sense, Comenius's textbooks—for all schools or grades—were up to date for his times. But what is more, Comenius adopted as a theoretical foundation for education the method Descartes claimed for mathematics, biology, and the like.

Conclusion

Whosoever worked out a didactic after Comenius in a strict sense came to almost the same principles and practical advice we find in Comenius's works. A prominent example is the Latin maxim *repetitio est mater studiorum* ("repetition is the mother of study"), which has been repeated in one form or another down to the present day. But the underlying *Weltbild* differs: Soon after Comenius, the theological one was replaced with the concept of Enlightenment.

So, for example, in Johann Bernhard Basedow's famous *Elementary Work* (1787), the matter is anthropocentrically organized; its copper plates–engraved illustrations follow a human's path from birth to death instead of presenting the history of the salvation of mankind. Furthermore, it is not the "world" as such that the *Orbis Pictus* and Comenius's other textbooks represent symbolically. It is rather the world of the Brethren, the world as seen with the eyes of a prominent member of that proto-bourgeois community. (Schoolbooks generally represent the specific *Weltbild* of a given society.) The didactic maxims are alike over the centuries, for they are always about teaching and learning. Nevertheless, there is a lesson didacticians have learned from Comenius and still can learn nowadays: Didactical reasoning and practical advice make sense only if grounded in a concept of human destiny.

Common Curriculum

The idea of a common curriculum is best grasped by contrast with differentiated, selective, or alternative curricula. Generally, differentiated curricula are grounded in the contingent personal, social, or other local circumstances of learners. Perhaps, the most famous defense of a selective or differentiated curriculum is to be found in Plato's *Republic*, where this philosopher distinguishes between persons of gold, silver, and bronze who are fitted by natural ability—and correspondingly appropriate education—to be, respectively, the ruling legislators (guardians), the administrators (auxiliaries), and the ruled workers of his ideal society. A well-known advocate for a common curriculum, on the other hand, was Mortimer Adler in the United States, who argued in the 1980s that the best education for the "best" in society was the best education for all—all students should embark on the same curriculum, although some would not progress as rapidly or as far as others. This common curriculum was a heavily academic one and represented—as Michael Apple put it—the "official knowledge" endorsed by a particular social class, the ruling elite. This entry first reviews the evolution of the common curriculum and then examines the philosophical assumptions that underlie it.

The idea that the educational course of study should not be uniform, but vary according to individual ability and/or social need, was historically influential; in Britain, for example, it was writ large in the 1944 Education Act, which assigned pupils, on the basis of examinations at age 11, to different sorts of academic (grammar) and vocational (secondary) schooling according to their "abilities and aptitudes." However, by the 1960s, such educational apartheid was widely seen as individually and socially unjust and divisive, and there was a major political shift in the United Kingdom toward abolition of the selective "11+" examination and the establishment of the so-called comprehensive schooling for all. In the United States, the situation was different; development of comprehensive high schools allowed a diverse range of options to appear on the curriculum—a "cafeteria" type of situation that arguably led to Adler's reaction in favor of a common curriculum and, eventually, culminated in the movement in the 21st century for common or core curriculum standards.

Eventually, experience with comprehensive schools in Britain led in the same direction. Although widespread, the shift to comprehensive schooling in the United Kingdom was not immediately attended by curriculum change—pupils of different ability largely pursued more or less distinct and separate courses of academic and vocational studies under the new comprehensive school roof. And so curriculum theorists and policymakers were drawn toward revision of such segregated courses in favor of a new comprehensive curriculum that might be pursued in common by *all* pupils (without "special needs"). From a philosophical viewpoint, however, it was clear that any such curriculum would need to be grounded in some defensible conception of common educational need that transcended the contingencies of individual psychological difference (of interest or ability) or local social convenience. The remainder of this entry will focus on the interesting philosophical arguments that emerged.

Despite widespread approval of comprehensive education in the name of justice and equality, it could not be fair to subject all pupils to the same educational treatment, if such equal treatment was more appropriate to some than others. Thus, the pressing question for curriculum theorists was that of finding a defensible rationale for common educational provision for pupils of widely varying intellectual range and socioeconomic status and background.

It was in the context of nascent comprehensive schooling in the United Kingdom that a number of postwar British educational philosophers—broadly located in an educational tradition harking back to 19th-century liberal educationalists such as Matthew Arnold and mostly located in the London Institute of Education—developed a view of education focused on the acquisition of a range of forms of knowledge and understanding held to be constitutive of a rational human mind. (It is interesting that a literature of similar complexity and sophistication did not emerge among philosophers of education in the United States, although political theorists such as Michael

Apple were quite prolific.) While the basic idea was pioneered by Louis Arnaud Reid (first incumbent of the chair of philosophy of education at the London Institute) in a book titled *Ways of Understanding and Education*, the notion was further developed by Paul Hirst in his widely influential paper "Liberal Education and the Nature of Knowledge" and given more practical curricular application by John P. White in his book *Towards a Compulsory Curriculum*. To be sure, such authors did not agree on all points, and there were parallel—and variable—developments of this general theoretical trend in other countries; but there was clearly enough common ground here to distinguish such thinking about a common curriculum from previous tendencies toward segregated and differentiated curricula.

To begin with, the basis of most, if not all, of such theorizing was *epistemological* rather than psychological, sociological, or political: It began from reflection on the nature and value of *knowledge* as the key goal of educational endeavor. In this light, the mind-constitutive forms of knowledge were to be regarded as of *intrinsic* more than extrinsic educational value; the (much misunderstood) point here is that if education is broadly construed as the development of rational minds, then the forms of knowledge are not mere *means to* education, they are what we *mean by* education. But then, all school pupils (apart from those with serious learning difficulties) should be considered equally entitled to educational exposure to the forms of knowledge and understanding required for the development of their rational mind.

It is crucial here to distinguish the epistemic notions of rationality and knowledge from the psychological notions of intelligence and ability—since, to be sure, agents may be intelligent but not very rational, or vice versa. On this view, it is not the job of education or schools to increase or develop intelligence (whatever that might mean); rather, it is to help all pupils acquire—to the best of their given abilities—those rational forms of knowledge and understanding whereby they may make meaningful sense of their world. According to Hirst and others, this would require some initiation of *all* pupils into the time-honored forms of human knowledge and understanding enshrined in scientific studies, logic and mathematics, human sciences, moral inquiry, artistic and aesthetic appreciation, and religious and philosophical studies. The first significant British (if not global) attempt to develop a new common curriculum for the comprehensive school, drawing explicitly on Hirst's forms of knowledge, was outlined in the Scottish Munn Report in 1977 and thereafter implemented in Scottish schooling in the form of the "Standard Grade" curriculum. Common curricula conceived broadly along these lines have since been developed in England and other countries.

Although much discussion of common curricula has focused on the pros and cons of a "common *compulsory* curriculum"—reflecting the fact that many, if not most, of latter-day common curricular developments (e.g., in the United Kingdom and the United States) have been subject to state mandate as "national curricula"—the philosophical issue of whether a common curriculum is educationally defensible and the political issue of whether it should be nationally or otherwise compelled are in principle separable issues. That said, it is not hard to see how philosophical commitment to the idea that *all* children are entitled to a common (at least core) educational experience has invariably led, for good or worse, to political efforts to secure such entitlement through state legislation.

Communitarianism

Communitarianism can be considered as being a thesis about the social construction of the self; that is, the individual self cannot be understood as separate from the social relations in which it is situated. For communitarians as diverse as Jürgen Habermas, Seyla Benhabib, Amy Gutmann, Iris Marion Young, Martha Nussbaum, Stanley Cavell, Eamonn Callan, and Jacques Derrida, individuals produce—and engage in—social practices and public institutions in which they collectively and deliberatively advance their own aspirations, values, and reasons. To the degree that educational theory and philosophy subscribes to a notion of education that in the Aristotelian sense refers to a social practice of reasoning together, an understanding of communitarianism that emphasizes the constitution of the self and its situatedness in social relations is called for. In this entry, congruent with the views of the aforementioned communitarians, three conceptions of communitarianism—conservative, radical, and pluralist—are first explained, in conjunction with the notion of education as a practice. Concurrently, education is examined as a practice embodying communitarian ideals such as public deliberation, responsibility, and disruption.

Conservative Communitarianism

First, conservative communitarianism accentuates communal inclusiveness and solidarity among people on the grounds that the social or cultural groups in which people grow and live share a common language, history, culture, identity, and ethnicity. Considering that such a form of communitarianism is associated with a patriotic loyalty to the group, educative relations have the potential to foster uncritical or unchallenged allegiance to the views of the group or community. Often, such relations are characterized by a relative lack of reflective thinking, and at times blind imitation, resulting in overzealous and dogmatic political and social action.

Radical Communitarianism

Second, radical communitarianism advances the view that communal relations are engendered on the basis of both equality and autonomy. On the one hand, each member of the community enjoys equal status on the grounds that all persons have an equal right to speak and to be listened to, irrespective of the fact that one member of the community may be considered to be more capable than another. On the other hand, in an autonomous, self-determined way, community members aspire to achieve—collectively—their political, social, and economic aspirations, without necessarily undermining the autonomous choices of individuals.

Pluralist Communitarianism

Third, pluralist communitarianism—the focus of this entry—has in mind the cultivation of public deliberation in what has been called an atmosphere of disruption. Whereas conservative and radical communitarianism both place a high premium on patriotism to the group as well as on equality and autonomy, pluralist communitarianism emphasizes public deliberation in disruptive ways that create opportunities to invoke the potentialities of individual members of the community. It is held that when people engage in public deliberation, they listen attentively to what others have to say and then respond so that all views are reasonably considered by one and all without repudiating the rights of anyone to be heard. Individuals can alter the conversation through modifying or adjusting views on the basis of more defensible justifications. In a way, pluralist communitarianism fosters a distinct conception of education that has democratic ideals and can be cultivated through at least three interrelated practices: (1) public deliberation, (2) responsibility toward the other,

and (3) (as will later be explained) disruption of the democratic order.

The Role of Public Deliberation

The first group of pluralist communitarians, namely, Habermas, Benhabib, and Gutmann, has in mind the use of public deliberation to guide educational practices. Public deliberation is aimed at empowering individuals to determine their rules of collective engagement and their cooperative living together through rational decision making based on a reflexive consensus. Through public deliberation, people offer reasons to justify their points of view, while being ready to listen to what others have to say in the quest to achieve agreement based on argumentation, persuasion, and the exercise of unconstrained freedom of articulation—except, as aptly stated by Gutmann (2003), when an injustice to others is being perpetrated (p. 47). Thus, when people embark on public deliberation, they endeavor to establish educational practices based on the construction of more reasonable views that others might find more palatable and through which people can together make modifications and adjustments to arguments that prevail. Hence, public deliberation considers argumentation, persuasion, and consensus making as reasonable endeavors to pursue in search of justifications that enjoy the support of an association of individuals as they embark on educational practices.

More specifically, on the one hand, Habermas's (1996) notion of public deliberation involves intersubjective communicative processes aimed at securing compromises, consensus, or fair bargaining based on a preponderance of "the better arguments" (p. 24). However, such a view of public deliberation presupposes that everyone is eloquent and capable enough of producing these better arguments. But of course, this is not necessarily the case. One may find that some people hold more persuasive views than others (who might not be able to articulate their cases eloquently and convincingly). On the other hand, Benhabib's (1996) notion of public deliberation is underscored by a condition of reflexivity whereby the outcome of deliberation is not fixed but can be revised and subjected to reexamination—that is, debated, questioned, and criticized (p. 72). In this way, even the consensus attained should not be considered as the conclusive outcome of deliberation, but rather, it should be seen as a temporary consensus until more reasonable judgments have been attained. Such a reflexive account of public deliberation would not silence or curtail dissenting minority viewpoints that a strictly consensus-oriented approach to public deliberation might dismiss. By implication, even "the best arguments" should be subjected to revision and reexamination, perhaps at a later stage; therefore, the outcome of deliberation is considered as an interim consensus until more reasonable opinions and preferences could confirm or overturn previously held views.

Relationships Based on Shared Humanity

The second group of pluralist communitarians, namely, Young, Nussbaum, and Cavell, offer an account of communitarianism that connects people on the basis of their humanity. One belongs to a particular group, and by virtue of being human, one bears an internal (organic or holistic) relation to all other human beings—especially those who might not belong to the same group as oneself. This internal relation with one's fellow human beings does not allow an individual to shed responsibility for what happens to others, even though they belong to a different social group.

Whereas Young establishes an internal relation among people on the basis of narratives about themselves that they exchange, Nussbaum considers such an internal relation to be based on the recognition of each other's vulnerability—that is, the putting of oneself in the shoes of others and actually doing something about changing their condition of vulnerability. As a member of a particular cultural group in society, one cannot just impose one's views (albeit religious or political) on others, for that in itself would deny that there are people in different positions (with different cultural orientations) than oneself. Doing so would be doing an injustice to others. Being responsible for what happens to them means that their views are acknowledged, even though one might not be in agreement with them. In short, one conceives the other from the other's point of view.

Pedagogically speaking, in demonstrating one's responsibility toward others in the manner described by Cavell, one immediately acknowledges one's capacity for intimacy with others—thus, limiting one's own idiosyncratic privacy. Thus, our private actions may lead to a betterment of our communal actions. One might privately contemplate doing something about improving human relations among people, but doing so autonomously without also penetrating the thoughts of other community

members may not necessarily contribute to achieving this goal. If one's privacy remains restricted to oneself, with the intention not to exercise responsibility to others, then one's practices would remain unshared and separated from the people with whom one happens to live. On the other hand, one's privacy opens a door through which someone else can tap into one's thoughts—which might be of benefit to society; but if this privacy is prompted by narcissism, the possibility that others might gain something valuable for the good of society could be circumvented. If one were to think about social practices in a balanced way, one should acknowledge the private efforts of individuals yet simultaneously recognize the possibility that their private actions can be of good public use.

Valuing Acts of Disruption

The third of a group of pluralist communitarians, represented by philosophers as diverse as Callan and Derrida, make a cogent case for acts of disruption in educational discourses. On the one hand, Callan's case for public deliberation characterizes the distress and belligerence of confrontation (i.e., a process of struggle) as moral truth is pieced together from the fragmentary insights of conflicting viewpoints. Whereas Habermas, Benhabib, and Gutmann view public deliberation as a mutually responsive act of engagement without belligerent contestation, Callan (1997) invokes ethical confrontation as constitutive of deliberation. For him, public deliberation is not an attempt "to achieve dialogical victory over our adversaries but rather the attempt to find and enact terms of political coexistence that we and they can reasonably endorse as morally acceptable" (p. 215). Through public deliberation, participants raise doubts about the correctness of the moral beliefs of each other, or about the importance of the differences between what they and others believe (a matter of arousing distress), accompanied by a rough process of struggle and ethical confrontation—that is, belligerence (p. 211). If this is what happens, belligerence and distress give way eventually to moments of ethical conciliation, when the truth and error in rival positions have been made clear and a fitting synthesis of factional viewpoints is achieved. This is an idea of public deliberation, where no one has the right to silence dissent and where participants can speak their minds. Thus, Callan's view of public deliberation is one of taking risks and being offensive, of causing disruption. (In light of this, it can be seen that some educators listening compassionately to students' narratives are culpable in that they steer the conversation so that the focus is on who the students are and not on the substance of what they have to say.)

On the other hand, Derrida's (2004) take on pluralist communitarianism can be explained by reference to his understanding of a "community of thinking" in the context of the university. Such a community would go beyond the "profound and the radical," and its enactment is "always risky; it always risks the worst" (p. 153). A "community of thinking" that goes "beyond" with the intention of taking more risks would become more attentive to unimagined possibilities, unexpected encounters, and perhaps to "the lucky find." Risky efforts on the part of academics and students would enhance the possibility of highly contemplative and theoretical contributions that go beyond practical usefulness and provide us with more to know than any other instrumentalist form of action (p. 130). Here, one is reminded of the need for risky intellectual contributions in educational practices, which might address the sporadic outbursts of violence and perpetual conflict in modern society. In a way, a "community of thinking" demands that reasons are rendered, encourages risk taking, and contributes toward renewal. In quite a disruptive fashion, a "community of thinking" allows us to take more risks, to deal openly with the radical incommensurability of the language games that constitute our society, and invites new possibilities to emerge—that is, a "community of thinking" cultivates a kind of thinking innately concerned with creating possibilities for dissent—a diversity of interpretations—complicating the taken for granted and opening up to the other.

Implications for Education

Finally, pluralist communitarianism offers a more positive way to think about education than do the conservative and radical views. Education as a democratic encounter requires both educators and students to act authoritatively whereby they both disrupt the pedagogical practices. That is, an educator acts authoritatively when she creates learning opportunities for students in terms of which they can play a role in interrupting the chain of reasons and consequences—causes and effects—that shape their learning. And learners are authoritative when they are enabled to create new forms of learning and to discover modes of action to make things happen.

By engaging in critique, the students have an equal ability to speak, understand, and redefine the practice of education in pursuit of making it a robust pedagogical encounter—that is, an encounter that has pluralist communitarian expectations.

Communities of Learners

The phrase *community of learners* is associated with a theoretical perspective on learning that, according to Barbara Rogoff (1994), "takes as a central premise the idea that learning and development occur as people participate in the sociocultural activities of their community" (p. 209), and with a broader pedagogical reform effort designed to transform K–8 classrooms into sites of deep thinking and authentic collaborative inquiry. Proponents of this reform agenda (see Bielaczyc, Kapur, & Collins, 2013) argued that traditional academic approaches—narrow tasks that emphasize memorization or the application of simple algorithms—will not develop students who are critical thinkers or students who can reason, write, and speak effectively. Instead, to develop these higher-order skills, students need to take part in complex, meaningful projects that require sustained engagement, the development of subject matter expertise, collaboration, research, management of resources, and the completion of an ambitious performance or product. This entry discusses the influential Fostering Communities of Learners (FCL) project designed by Ann Brown and Joe Campione (1994), which is widely regarded as a model program for fostering such skills in students. An outline of the program and its theoretical grounding in "first principles of learning" is followed by a description of its implementation in the classroom through a variety of student activities. The entry concludes with a brief critique of the program's general applicability for curriculum design.

FCL Content and Teaching Strategy

The content in FCL introduced K–8th grade learners to key ideas in the life sciences: biodiversity, adaptation, evolution, species survival, and interdependence. The social life of the classroom-learning community was organized to foreground scientific dilemmas and uncertainties and to hand over intellectual authority for making sense of these to students through research, debate, reading, and writing.

Although it was the application of FCL that was recognized for its significance, Brown (1997) saw the project as having a dual focus on learning theory and practice. For her, the classroom was a living lab and only one site for her research program, which was organized to develop a theoretical model of learning and instruction, rooted in empirical data. Some of her influential earlier work was focused on the topic of metacognition—that is, the capacity to think about one's own thinking and to intentionally apply strategies to improve learning. Her basic studies of reading comprehension with her student Anne Marie Palincsar eventually became the basis for a core instructional strategy in FCL: reciprocal teaching, discussed further below (Palincsar & Brown, 1984). The development of metacognitive capacity and repertoires of learning strategies were basic to the FCL model. They ultimately sought to develop "intelligent novices" who were lifelong learners prepared to develop expertise on an issue as needed.

Theoretical Grounding in Learning Principles

FCL is based on a set of "first principles of learning." Reflective of the interdisciplinary field of the learning sciences, these principles were grounded in contemporary social, cognitive, and developmental psychological research, as well as perspectives from sociology, linguistics, sociocultural theory, and the philosophical and pedagogical ideals behind early renditions of project-based learning. Brown (1997) articulated six learning principles:

1. The importance of agency or learners, efforts to attain understanding through dialogue
2. The benefit of collaborative learning arrangements that distribute expertise and foster interdependence
3. The importance of reflection encouraged by an intentionally metacognitive environment
4. A culture of learning that values negotiating ideas and contributing to the classroom community and beyond
5. Designs crafted around developmental corridors of understanding that are supported by a spiraled curriculum that revisits topics over years to advance learners' competencies for reasoning about complex topics in particular domains
6. Lev Vygotsky's (1978) concept of the zone of proximal development (ZPD), or the difference between what a child could accomplish alone versus with the help of others, was another core idea that helped organize FCL classrooms. FCL classrooms were conceptualized as being constituted by multiple overlapping zones of proximal development that included not only adults with more expertise but also peers, books, videos, visual representations, and computing tools. Learning within a zone of proximal development is characterized as a process of appropriation in which learners come to take on independently those activities and strategies that were initially supported by social and material resources.

The articulation of first principles was intended to help avoid a phenomenon captured in the phrase *lethal mutations*, in which teachers apply instructional routines in a procedural way, distorting the original goals that these were designed to promote. At the same time, the research and design team were aware of the importance of systematically studying and redesigning teaching routines that mapped onto these principles and could be generalized to other content. Thus, the FCL instantiations of "first principles" were continually revised based on findings from the lab and from classroom design experiments (Brown, 1992), a methodological approach pioneered by the FCL team and their colleagues for advancing both theory and practice. Significant gains in reading comprehensions, generation of analogies, and content knowledge were documented (Brown, 1997), and collective knowledge-building practices evolved through observational and comparative studies. The program of research on FCL continued after the unexpected death of Brown in 1999. One set of studies culminated in a situated account of transfer (Engle & Conant, 2002). This work focused on classroom interactions and explored the hypothesis that transfer would be related to whether teachers framed learning as temporally linked to past and future contexts and whether they framed students' contributions as relevant to a broader community of people interested in the same topics. This interactional approach to studying FCL relied on video records collected in classrooms years before and demonstrates the potential of design experiments to continue to yield theoretical insights about the nature of learning over time. Other work in the FCL tradition focused on teacher learning.

Engineering a Community of Learners in the Classroom

The FCL first principles were brought to life in the classroom through an interconnected system of student activities that followed a tripartite cycle of research or inquiry, teaching others what was learned through research and culminating with the completion of a consequential task to represent the synthesis of group work. In a typical FCL unit, student groups would choose an animal species to focus on, and then individual group members would each take on one of the core disciplinary ideas to develop expertise around it in a process called *majoring* in the FCL terminology. For example, in a unit on endangered species, group members focused on mechanisms related to survival, including protection from predators, acquisition of food, and reproduction (Engle, 2006). Within the broader research–teach–synthesize cycle, participation structures for collaborative groups and lesson formats/

routines were designed to support the deeper goals of engaging learners in dialogue and complex reasoning. *Benchmark lessons*, for example, were whole-class activities where the teacher shared new content. *Cross-talk* sessions involved whole-class dialogues in which debates and differing perspectives could be articulated. *Research rotations* were organized for small groups to engage in collaborative sessions to co-comprehend texts or use the computer to do research. *Jigsaw* activities required learners to share their particular content expertise with group members, and then groups would recombine to share species-specific knowledge with other groups. The culminating projects were designed to motivate yet a deeper level of understanding. Students were expected to present their work to an audience—to groups of visitors, parents, and other students. These presentations were in the service of the metacognitive goals central to FCL, as described by Brown (1994): "Audiences demand coherence, push for high levels of understanding, require satisfactory explanations, request clarification of obscure points. . . . There are deadlines, discipline, and most important, reflection on performance" (p. 8). Presentations of work also signal to students that their work is important enough to be a source of public learning and celebration and provide opportunities for others in the learning community to see, appreciate, and learn from student work.

Challenges and Controversies

Although considered a model of a theoretically grounded curriculum, the FCL project also has its critics. One concern centers on the text-based nature of the inquiry work. Given Brown's prior focus on metacognition in the context of reading comprehension, this emphasis is not surprising. However, many science educators favor experiential approaches that have learners design and carry out investigations in the natural world. A second concern is that FCL is not easy for teachers to implement or adapt for their own content. The curriculum design requires domains that can be subdivided into subtopics that have interdependent relations and are "jigsaw-able." A third challenge stems from concerns about whether first principles are a useful way to describe and disseminate novel pedagogies. This critique arose in part from an ambitious project, funded by the Mellon Foundation, that brought FCL together with two other leading reform efforts in a project called Schools for Thought (see Lamon et al., 1996). The goal of this effort was to create a synergistic model that could transform an entire curriculum. This unique collaboration raised a number of questions as researchers in each site tried to implement their colleagues' ideas. They found that the first principles were subject to multiple interpretations. Despite these critiques, the FCL has been the basis of numerous curriculum efforts spanning mathematics, science, and language arts and remains a preeminent example of a theoretically and empirically grounded instructional approach.

Competence

Although the term had been used in the fields of sociology, literary criticism, and linguistics, it was not until the 1980s that *competence* entered the educational lexicon, chiefly as a result of its employment in the competence-based education and training (CBET) system, which underpinned the reform of vocational qualifications in the United Kingdom led by the National Council for Vocational Qualifications (NCVQ). In terms of its standard denotation, competence is normally connected with the satisfaction of certain criteria of action, thought, or behavior: the performance of an act or process according to generally accepted standards or evaluation principles. It is in this sense that we might speak of a competent plumber who is able to install relatively problem-free sinks or central heating systems, a competent chess player or athlete who succeeds in a good many of the games played or events entered, or a competent scientist who has a reasonably good record in terms of papers published or funding applications granted.

Although competence can theoretically refer to a person's potential capacity, its primary characteristics connect it squarely with the outcomes of action and behavior, with what a person has actually done or demonstrated when judged by certain standards. An accompanying feature is the implication that achieving competence in any particular domain may not be the highest form of accomplishment possible. This observation brings in some of the more negative connotations of the concept. In addition to the fact that, as Terry Hyland's critiques over the past few decades have argued, there are a good many categorically different definitions of competence in the literature—as well as a systematic confusion between *competence* (as a capacity, applying to persons) and *competency* (as a disposition, applied to specific abilities, skills, or activities)—there is a strange ambiguity about the term. Although competence is generally a term of approbation, it also carries with it minimalist characteristics. Dictionary definitions that include synonyms such as *adequate*, *sufficient*, and *suitable* tend to confirm the idea that describing a person as being a competent doctor, electrician, teacher, or golfer is, perhaps, not the highest form of praise for or evaluation of that person's abilities or achievements.

The minimalist connotations are exhibited in a number of ways. The overwhelmingly predominant employment of "competence-speak" is in the area of vocational education and training (VET), especially the utilization of CBET in the introduction of national vocational qualifications (NVQs) by the NCVQ. Gilbert Jessup, the erstwhile director of research for the NCVQ, was only too aware of the "basic minimum" overtones of the central concept of competence and attempted to counter this by asserting that competence did not refer to a basic minimum level of performance but to the standard required to perform an occupational function. But such special pleading did little to answer the suggestion that perhaps such a standard was not the highest one possible. For example, in a number of widely used models of professional/occupational development, competence is only approximately a halfway stage on the journey people make from the status of novice to that of expert. Thus, competence does not seem to be the most appropriate foundation on which to build a whole system of education and training and, at this level, is arguably as fatuous and nebulous as its ubiquitous sister term, *skill*.

Competence and Vocational Education

The chief reason that competence is of any interest to educators is, without doubt, its widespread employment in the field of VET, especially in the development of NVQs in the United Kingdom. Following the U.K. experience in the 1980s, CBET systems were introduced in countries around the world in the hope of finding quick-fix solutions to the difficult challenges of neoliberal economics and post-Fordist industrial restructuring. The results have generally been disappointing. In the survey of the implementation of CBET systems in countries around the world edited by Antonio Arguelles and Andrew Gonczi, the editors concluded that CBET did not satisfy the requirements for innovative skill development in industrial and professional contexts and that its educational foundations were shaky. In the United Kingdom, the NCVQ was abolished in

1997, general NVQs were phased out in 2008, and, although NVQs still operate in specific spheres of workplace learning, they no longer have such a central place either in apprenticeship schemes or VET in general. A number of recent reports on vocational education in Britain have indicated that competence qualifications do not meet the demands of employers or students, and apprenticeships in particular have a more general educational foundation now.

Weaknesses of CBET

The demise of the competence model is due to a number of educational difficulties with CBET. In addition to the logical and linguistic problems noted above, there is epistemological confusion concerning the relationship between competence and knowledge, theory and practice, and knowing-how and knowing-that. Since there is an insistence that CBET measures only performance outcomes, knowledge thus comes to serve a purely instrumental purpose: It is only valuable if it gives rise to measurable performance outcomes. Such a devaluing of knowledge and understanding—conjoined with the marginalization of moral and affective objectives in competence systems—tends to downgrade VET, as a number of critical studies and national surveys have pointed out over the years. Moreover, the obsession with product and neglect of process is underpinned by a behaviorist thrust that is at odds with contemporary developments in education—and also in craft apprenticeships—which foreground autonomous and independent learning.

Conclusion

The logically imprecise, epistemologically confused, and behaviorist foundation of CBET serves to rule out its widespread adoption by educators and policymakers concerned with autonomous student learning and a liberal education as outlined by R. S. Peters, which is connected with the development of knowledge, understanding, and values. The education of the whole person—especially in that broad conception of vocational studies informed by John Dewey's philosophy—requires rather more than the satisfaction of performance criteria in the pursuit of competence outcomes.

Complexity Theory

A simple example of complex behavior is a group of birds in flight, flocking together in a beautiful unfolding pattern. Fascination with complex behavior is as old as civilization, but progress in understanding it theoretically has been slow. From the scientific revolution of the 17th century until recently, scientists assumed that natural systems could be simplified and approached by linear methods. Differential and integral calculus focus in on small segments of curves to reduce them to lines. The dominant analytical paradigm has prevailed because of the availability of methods of linear analysis, not because of any deeply argued conclusions about nature.

Complex systems, however, are nonlinear. Progress in understanding them was made in the 20th century owing to mathematical advances in nonlinear dynamics and to computers that were able to make complicated calculations and simulate complex processes. Studies of complexity and self-organizing systems converged in the field of complexity theory during the 1980s. As is common in new interdisciplinary fields, those approaching the territory from different starting points have imported different interests, problems, methods, and terminologies. It is now a truism that there is not even basic agreement about the definition either of "complexity" itself or of related central terms such as *self-organization* and *emergence*. Nonetheless, consensus definitions are emerging, and these terms have demonstrated enormous heuristic value in suggesting analogies and models in a number of areas of study, including education.

Key Ideas of Complexity Theory

In complexity theory, a *system* is defined as a set of interacting parts that behave as a whole and can

be distinguished from an *environment* by identifiable boundaries. The system's function depends on the nature and arrangement of its parts. Because some parts interact, they are often referred to in complexity studies as *agents*. Systems may include one or many diverse types of agents: for example, army officers and enlisted men, classroom teachers and students, and business managers and workers. Agents of any type can follow similar or different rules, so there can be variation not merely among the agents but also among the rules or strategies. Systems also include nonagents, such as artifacts, which are used and acted on by agents.

The pattern of interactions among parts of the system determines the system's structure. A system is said to be complex to the extent that there are strong interactions among the parts, interactions that significantly influence the probabilities of many kinds of future events, including the subsequent actions and strategies of agents. Interactions in a system are more likely to be strong when there are many and diverse agents following diverse local rules or exhibiting diverse local strategies. The more complex the system, the stronger and more multiple the interactions, and the more difficult it is to interpret, predict, or control its behavior.

A *complex adaptive system* is one where the agents in the system seek to adapt to changing conditions in the system or the environment. Adaptation involves making selections (of agents, agent types, rules and strategies, or artifacts) in the system to improve the performance of the system's, or of an individual agent's, performance on some measure of success. An organization exists in a competitive environment, and the adaptive success of any selection (e.g., of personnel or strategies) depends not just on these selections but also on the success of selections of competitors in the environment. The environment is referred to as a *fitness landscape*, in which the fitness (capacity for organizational success and durability over time) of an organization rises and falls as a result of both the organization's adaptive selections and those of its competitors.

Complex human systems such as organizations are inherently adaptive. Humans draw on their rational, calculative side to state explicit goals and to devise through trial-and-error or experiment-effective strategies as means for achieving them. Complexity theory views system goals as tools to focus agent efforts: Goal achievement is not the same as fitness, as goals can be poorly chosen, and their achievement can accompany suboptimal system performance or even system failure in the system's changing environment.

Self-Organization and Emergence

Some systems, and especially those of interest to the field of complexity studies, take shape or form a structure "by themselves"—that is, through the interactions of agents following local rules rather than through top-down control. The flocking of birds, much studied and modeled by complexity theorists, is a paradigm of such systems, which are said to display *self-organization*.

Complexity theory seeks general principles about the growth and evolution of structure in systems to understand how changes in control parameters of the system—such as the number and diversity of interacting agents and strategies, the rate of flow of information in the system, and the strength of interactions—affect system components and their interactions. Changes in such control parameters affect the stability of organizations and their parts and can prompt phase transitions to different structures when the system operates at the edge of chaos or disorder. According to complexity theory, it is possible to control phase transitions in complex adaptive systems by manipulating control parameters even though the structure of the posttransition system cannot itself be predicted or controlled.

Complex systems are marked by *nonlinear causality*; that is, the causal relationships in the systems cannot be interpreted as linear or continuous functions. In systems tending to equilibrium, such as physiological systems in equilibrium, small positive feedback loops are balanced by negative feedback loops, so that linear mappings remain good approximations of cause-and-effect relations. Complex systems, however, operate far from equilibrium conditions; they are marked by unchecked positive feedback loops, so small changes in causal factors can have large and unpredictable effects.

When a system is destabilized by such a positive feedback process, it can fall into gross disorder, but significantly, it can also enter a phase transition to a new order at what is called the *edge of chaos*. (The term *chaos* in complexity theory retains its ordinary sense of disorder or disarray; it is not to be confused with the term as used in *chaos theory* to refer to an unusual type of order.) New structures, exhibiting new properties not previously witnessed in the system, may then emerge owing to processes of self-organization.

Three properties are characteristic of emergence. First, the new structure is entirely dependent on the interactions of the underlying parts—this property is often referred to as *supervenience*. Second, the emergent properties are not predictable on the basis of the properties of the parts—this is referred to as *holism* and is often expressed by saying that "the whole is greater than the sum of its parts." Third, once the new whole takes shape, it has significant effects on the behaviors of the parts—this is known as *downward causation*.

The central idea about organizational change in complexity theory is that organizational adaptations result from self-organized emergence rather than from central control. Functional stability and order are continuously maintained not through planning, top-down strategy, and tight control of operations but through successions of creative interactions at the edge of chaos that may be provoked or coordinated by leaders, but whose outcomes cannot be controlled. Leaders of organizations as complex adaptive systems cannot achieve top-down control because the causal links between the means at their disposal and the ends they seek simply cannot be mapped. To provoke change, organizational leaders can at best provoke phase transitions, so that a new, though unpredictable, adaptive order can emerge through self-organization.

The Classroom as a Complex System

A school classroom can be conceived as a complex system comprising teachers, learners, and artifacts such as pencils, worksheets, desks, and blackboards. In a typical classroom, information flow is determined in a top-down fashion in a curriculum established by reference to local, state, or national standards. Teachers convey preselected subject matters to learners and monitor learning with recitations and objective tests. In this way, a certain kind of order is maintained.

Complexity theorists view this kind of top-down structure as maintaining a suboptimal order by reducing complexity—suppressing differences among both teachers and learners as agent types possessing diverse strategies. The containment of these differences, while maintaining a rigid order, can also result in a breakdown of order as students act out in rebellion—hence the emphasis on classroom management strategies in teacher preparation.

Complexity theory suggests an alternative approach for fostering classroom order—releasing the complexity inherent in diversity by reducing top-down control, liberating learner action within given limits, and harnessing educational value from local interactions that ensue.

In *The School and Society*, John Dewey anticipated such an approach to classroom organization in all of its key elements, via a shift from fixed lessons to activities grounded in social occupations such as crafts, gardening, and cooking. The complexity in the classroom situation is released, because students reappear as distinct agents with varied aims and action strategies: "The moment children act they individualize themselves; they cease to be a mass, and become the intensely distinctive beings." He notes,

> As one enters a busy kitchen in which a group of children are actively engaged in the preparation of food, the psychological difference, the change from more or less—passive and inert recipiency and restraint to one of buoyant—outgoing energy, is so obvious as fairly to strike one in the face. (Dewey, 1976, p. 11)

He adds that

> to those whose image of the school is rigidly set the change is sure to give a shock. . . . There is a certain disorder in any busy workshop; there is not silence; persons are not engaged in maintaining certain fixed physical postures . . . they are doing a variety of things, and there is the confusion, the bustle, that results from activity. (Dewey, 1976, p. 12)

But as the learners interact in accord with local rules, in a situation defined by inherent aims and limits (cooking a meal with the ingredients on hand), a discipline "of its own kind and type" develops, preventing the bustle and confusion from flying off into chaos. Instead, "In an informal but all the more pervasive way, *the school life organizes itself* [italics added] on a social basis" (Dewey, 1976, p. 12).

Complexity theory points to further analyses of and research on classrooms, schools, school districts, and other educational organizations as complex adaptive systems. It predicts that organizations will be capable of more optimal function through the release of inherent complexity—greater diversity of agent types and strategies, freer flow of information—and the subsequent harvesting of heretofore obstructed educational values.

Conceptual Change

Research on conceptual change has emerged in recent years as an important area in developmental and educational psychology. Conceptual change research investigates knowledge acquisition processes both in child development and with older learners, particularly in situations where the new information to be learned is very different from learners' prior beliefs and requires the radical revision of prior knowledge and/or the creation of new concepts.

The problem of conceptual change became first apparent to philosophers and historians of science in their attempts to explain how scientific theories change. According to T. S. Kuhn (1970), normal science operates within sets of shared beliefs, assumptions, commitments, and practices that constitute "paradigms." Discoveries emerge over time that cannot be accommodated within the existing paradigm. When these anomalies accumulate, science enters a period of crisis, which is eventually resolved by a revolutionary change in paradigm. Many scientific revolutions, such as those fueled by the Newtonian theory in physics, the Copernican theory in astronomy, and the Darwinian theory in biology, can be seen as the products of radical conceptual change. As Paul Thagard (1992) notes, in these cases, new theories are generated to explain known and new phenomena, and new concepts are formed.

Ideas about conceptual change from the history and philosophy of science were brought to developmental psychology through the work of Susan Carey (1985) and to science education through the work of George Posner, Kenneth Strike, Peter Hewson, and William Gertzog (1982). By the late 1970s, it had become apparent that students bring to their learning of science alternative frameworks, preconceptions, or misconceptions—some of which are rather robust and difficult to extinguish through teaching. In some cases, these alternative frameworks appeared to be similar to earlier theories in the history of science, for example, the impetus theory in mechanics (McCloskey, 1983). George Posner et al. (1982) drew an analogy between the concepts of normal science and scientific revolution offered by philosophers of science such as Kuhn (1970), and Jean Piaget's (1970) concepts of assimilation and accommodation, and derived from this analogy an instructional theory to promote "accommodation" in students' learning of science. According to Posner and his coworkers, students need to undergo a radical conceptual change when it comes to learning scientific concepts like *force*, *heat*, and *energy*.

Over the years, a significant body of research emerged that investigated the processes of conceptual change, the learning mechanisms involved in the generation of new concepts, and the instructional strategies that can promote it. The theoretical and methodological discussions that have taken place in this process have been some of the most interesting in the field of learning and instruction, raising important questions about the nature of knowledge, its organization, and its revision. Although the beginnings of conceptual change research can be traced to scientific discovery in physics and physics education, this research is by no means restricted to physics but makes a larger claim about learning that transcends many domains of knowledge and can apply, for example, to biology, psychology, history, political science, medicine, environmental learning, and mathematics.

Some researchers are not persuaded that there is a need to distinguish "conceptual change" processes from learning in general. However, while conceptual change is undeniably a form of learning, it is important to differentiate it from other types of learning because it requires fundamental changes in the content and organization of existing knowledge. It also requires the development of new learning mechanisms, mechanisms appropriate for deliberate knowledge restructuring and for the generation of new concepts. Most learning is implicit and additive involving mainly the enrichment of prior knowledge. Conceptual change cannot be achieved through the use of implicit, enrichment-types of learning mechanisms alone. In fact, the use of enrichment-types of learning mechanisms in situations that require conceptual change can often lead to the creation of misconceptions or "synthetic" conceptions. Synthetic conceptions are hybrid constructions that combine scientific information with intuitive beliefs and presuppositions based on everyday experience. In an example described by Stella Vosniadou and William Brewer (1992), young children often interpret scientific information regarding the spherical shape of the earth to mean that the earth is circular but flat like a pancake, or that the earth is spherical, but people live on flat ground inside it. These types of misconceptions are synthetic constructions suggesting that students are implicitly assimilating the new information regarding the spherical shape of the earth into their intuitive model of a flat earth. Similarly, erroneous strategies used by students in mathematics, such as the common mistake that 1/3 + 1/3 = 2/6 instead of 2/3, reveal the implicit interference of natural number operations in fraction addition (see Vamvakoussi & Vosniadou, 2010, for many more examples).

There are various theories that attempt to explain students' difficulties in situations where conceptual change is required. One approach, described by Andrea diSessa (1993), is known as "knowledge in pieces." According to this approach, the knowledge system of novices consists of an unstructured collection of many subconceptual elements, which become organized into a larger system of complex knowledge structures. This approach emphasizes the importance of knowledge integration in conceptual change processes.

Another approach, known as the "framework theory" approach, claims that children construct a naive theory of physics that is based on everyday observations in the context of lay culture, well before they are exposed to systematic science instruction. When exposed to scientific explanations, students use the usual, constructivist, and enrichment-types of knowledge acquisition mechanisms to incorporate the new, incompatible, information to their background knowledge. Because of the incompatibility between existing knowledge structures and the new, to-be-acquired, information, however, such learning processes may lead either to internal inconsistency and, thus, to fragmentation, or to the formation of synthetic conceptions. According to this approach, conceptual change is difficult because it requires the creation of new ontological categories, new representations, and the development of a constructivist epistemology. Other researchers, such as Michelene T. H. Chi (2008), also argue that conceptual change is difficult because it requires shifts in the ontological category to which a concept is assigned. Finally, sociocultural approaches focus on the influence of context and consider the engagement in contextually appropriate discourse as a necessary component of a learning environment that fosters conceptual change (Hatano & Inagaki, 2003).

In addition to cognitive and situational factors, conceptual change also seems to be affected by various motivational factors, such as goals, self-efficacy, interest, and academic emotions. Although research is still scarce, some findings indicate that students who adopt a mastery goal orientation engage in more elaborative cognitive and metacognitive self-regulatory strategies than students who do not adopt a mastery goal orientation are thus more likely to achieve conceptual change. Confidence in one's ability to perform well in a particular task or domain may also influence performance through a more effective processing of the material to be learned. However, high self-efficacy may also have detrimental effects on conceptual change. High confidence in erroneous beliefs often generates resistance to revision and commitment to current conceptions.

Despite their theoretical differences, most researchers agree that conceptual change is a gradual and time-consuming affair that is difficult to achieve. Instruction for conceptual change requires substantial changes in curricula and extensive sociocultural support. Dialogical interaction, argumentation, collaboration, classroom discussion, and meaningful practices around carefully designed curricula based on students' learning progressions are the means of developing prolonged motivation for change, metaconceptual awareness, epistemological sophisticating, and deep comprehension

activity, all of which are important facilitators of conceptual change (Hatano & Inagaki, 2003; Vosniadou, Ioannides, Dimitrakopoulou, & Papademitriou, 2001).

Instruction for conceptual change is often associated with the use of cognitive conflict. Cognitive conflict can be produced by asking students to make predictions or give explanations of phenomena and then present them with contradictory experimental evidence or some other kind of anomalous data. As John Clement (2008) has noted, despite various criticisms of the use of cognitive conflict, research shows that a combination of dissonance with knowledge building strategies can be fruitful in promoting conceptual change. In recent years, cognitive conflict has been used in a particular type of text structure known as refutational text. A refutational text states readers' alternative conceptions about a topic explicitly and then directly refutes them, introducing the scientific concept as a viable alternative. The superiority of refutational text compared with traditional expository text has been documented in many studies.

Other instructional strategies that have been found to promote conceptual change involve the use of instructional analogies and model-based reasoning. Instructional analogies are explicit analogies in which an unfamiliar concept or explanation is introduced by appealing to its relational similarity to a familiar concept from a different domain. Several models of how to teach with analogies have been developed, all of which emphasize, among others, the need to (a) use well-planned analogies from a base domain highly familiar to students, (b) make the mapping between the base analog and the target concept clear and explicit, and (c) indicate where the analogy breaks down to avoid the creation of misconceptions.

Finally, some researchers focus on models and qualitative model construction and revision as an important mechanism for conceptual change. By constructing explanatory models, students translate the verbal and abstract theories and explanations of science into concrete representations that can be explored and examined. A number of innovative curricula have been developed that start with children's views and slowly build new representations and understanding through model-building activities. These approaches have been consistently more effective in bringing about conceptual change compared with standard physical activities in science.

Although a large body of empirical evidence pointing to the problem of conceptual change has been accumulated, the relevant findings and results have not yet found their way into everyday classroom practices. Most teachers are unfamiliar with the kind of students' pre-instructional conceptions that have to be taken into account when new concepts are introduced. Indeed, teachers' views of teaching and learning are so limited when seen from a conceptual change perspective that some researchers have argued that teachers themselves need to undergo a process of "pedagogical conceptual change" (Duit, Treagust, & Widodo, 2008).

In conclusion, instruction-based conceptual change research investigates learning processes that require the substantial revision of prior knowledge under conditions of systematic instruction. Conceptual change research has shown that many concepts are difficult to understand because they violate people's intuitive beliefs constructed on the basis of observational experience in the context of lay culture. Conceptual change is difficult to achieve and requires many years of concentrated instruction and the design of innovative, research-based curricula that take into consideration the students' point of view, meaningful practices, and extensive sociocultural support.

Confucius

Confucius (551–479 BCE, China) was the first philosopher to offer systematic views on the values, purposes, and methods of education. While working as a consultant on classics, morality, rituals, and statecraft and holding offices to implement his ideals of good government, Confucius started his own school. It was one of the first in China. Confucian views on education have strongly influenced the educational systems and policies of China, Taiwan, Japan, and Korea for more than 2,000 years. The essence of his thought is that education is a learner-initiated quest for human excellence, which is of supreme value for individuals and society. The major source of his philosophy is the *Analects*, a collection of his teachings and conversations with his disciples. It was compiled after his death by his students. This entry discusses the purpose of Confucian education and its emphasis on virtue, his teaching method, and his conception of learning.

The Purpose of Confucian Education

For Confucius, living virtuously is the highest goal of life. Education is necessary for the realization of this supreme goal. Confucius believes that there is the Way (*tao*) for human beings, and following it is necessary to live the best life. The Way is realized when people possess and practice the virtue of humaneness (*ren*). For Confucius, humaneness is the most comprehensive virtue and includes filial piety, elderly respect, and sincere observance of rituals, righteousness, truthfulness, sincerity, and wisdom. The cultivation of these virtues necessarily requires education. This is because all people are the same at birth and are by nature neither good nor bad. Some become virtuous, however, due to proper training, and others become vicious, due to improper training. Training is practice in a form of behavior: either virtuous or vicious. In a nutshell, education, for Confucius, means education in the virtues, and practice is essential.

Education is not just to enable an individual to lead a flourishing life, however, but to enable the creation of a flourishing state. Rulers must follow the Way and cultivate the virtues. This is very important for Confucius, since he believes that rulers and officials can realize the Way in government and can create a good state, only through the practice of the virtues. The mere establishment of laws and policies is not enough. If rulers and officials live virtuous lives, citizens will imitate them and cultivate the virtues in their own lives. Confucius says, if the rulers practice rituals, reverence, righteousness, and truthfulness, the people will practice the same. In that case, people from other states will come to live under such rulers. The state will flourish with virtuous and able citizens. The flourishing of a state, then, depends on the education—the learning—of citizens, rulers, and officials of the government.

Virtue Education and Practical Knowledge

Confucian education is education in the virtues. In Confucius's view, education in technical and practical knowledge has low or minimal value. This is true even of the technical and practical knowledge of government officials. He claims that a person aspiring to be excellent shouldn't aim at fulfilling a specific role in society that requires only role-related knowledge. However, Confucius does not look down on common people or denigrate the importance of practical and technical knowledge in society. His strong emphasis on virtue education means

only that the worthiness of a person as a human being is determined solely by possession and practice of the virtues and that the cultivation of the virtues is prior to the practice of statecraft as such, even for government officials. Confucius's position is that after one has cultivated and practiced the virtues, one can and should pursue practical and technical knowledge.

Confucius's Teaching Method

Education, as the key to the flourishing individual and state, should be centered on studying and learning rather than on teaching and instructing. What is necessary for the cultivation of the virtues is practice of the virtues initiated by the learner. Without learning, Confucius claims, the quest for the cultivation of the virtues achieves only folly and vice. For example, the aspiration to be courageous results in rebelliousness without learning to be truly courageous. Also, the virtues cannot be cultivated externally, without the aspiration or desire for them. Confucian education is thus a learner-initiated effort to learn. For this reason, Confucius says very little about the efficacy of various teaching techniques, even though he himself was a dedicated teacher with his own unique methods. The role and function of teachers are limited, at least compared with what has become customary in the Western world today. A person is fit to be a teacher, Confucius says, if he is a transmitter of time-honored traditions and knowledge and a practitioner of acquired new wisdom through the study of the classics and the practice of virtue. Confucius takes no one else to be qualified as a teacher.

It is a mistake to take this to mean that Confucius is an educational reactionary and denies the efficacy of good teaching techniques. His methods show otherwise. They are designed to promote thought, in an effort to strengthen learning, reinforce the virtues, and solidify good social practice. He prefers the Socratic elenchus to long lectures and frequently asks his students questions, as well as answers questions posed to him by his students. The conversations that ensue are filled with concrete illustrations and analogies drawn from the classics, rather than with abstract and theoretical concepts. And Confucius's comments and questions are always geared to the level of intellectual and moral development of his interlocutors. He reasons together with his students to investigate an issue. Challenges from his students were also welcomed by him. He even describes one of his disciples as stupid because he didn't contradict Confucius. Critical thinking is more than encouraged—it is required—in Confucian learning. Confucius's teaching techniques are thus designed to acquaint students with received wisdom as well as to invite new insights. True Confucian education is therefore quite different from what has become known and practiced as "Confucian education." Knowledge as rote memorization of the classics, with uncritical acceptance of what the teacher hands down as wisdom, is a pleasant and simple picture of Confucian education, but it is nothing more than a gross caricature.

Confucius on Learning

Learning has the cultivation of the virtues as its goal, and Confucius believes that learning must begin with the aspiration of the learner. Learning then progresses with critical thinking, respectfully directed on accumulation of knowledge and on oneself. The study of culture and the classics is essential for learning. But learning is never divorced from life. Learning is fully realized in the practice of virtue in life. For Confucius, learning comprises aspiration for the cultivation of the virtues, the active accumulation of materials (especially the classics) for study, critical thinking on the accumulated materials and oneself, and the practice of what one has learned. All are inextricably linked.

This view of learning is exemplified in Confucius's own life. His lifelong aspiration to learn, he said, began at the age of 15, when he decided that the goal of his life was learning. Such a decision is necessary but not sufficient for learning, he realized. Immersion in the classics and critical reflection are also necessary. Much wisdom can be found in the classics, he discovered, but not as mere formulas or dry facts. Wisdom requires active reflection on the accumulated wisdom found there and elsewhere, and the accumulation of wisdom through critical thinking on accumulated wisdom is learning. However, wisdom attained through learning is not merely from studying many things and remembering them. He claims that learning without thinking is fruitless and that thinking without learning is perplexing. Learning in the sense of studying and memorizing the wisdom of others, without thinking, leads to misunderstanding, while thinking without any substantial acquisition of the wisdom of others leads to confusion. The sort of thinking that is required for true

learning is critical thinking, and it must take as its object knowledge attained from the study of the classics and the wisdom of others. In fact, thinking on such valuable accumulated materials to regain old wisdom for oneself and to attain new insights for new problems and questions is what critical thinking is.

In addition to critical thinking on accumulated materials, critical self-reflection is also an essential component of Confucian learning. Reflection on one's capacities, strengths, weaknesses, and limitations duly humbles a person and makes him open not only to the possibility of his own mistaken views but also to the teaching of others. The expected results of such critical self-reflection can again be seen in Confucius's own life: flexibility of thought, open-mindedness to ideas, humility in all matters, skepticism about the absolute certainty of one's knowledge, and candid admission of one's own limitations and weaknesses. Critical self-reflection is one of the pillars of Confucian thinking and helps strengthen critical thinking on accumulated materials.

Learning's ultimate aim is the practice of the virtues, not merely their possession. Virtues such as filial piety, respect for the elderly, sincere observance of rituals, truthfulness, righteousness, and wisdom are cultivated and completed through repeated and habitual practice. For Confucius, education is a life-transforming effort in the practice of the virtues by the learners themselves.

Connoisseurship and Educational Criticism

Educational criticism is an aesthetically grounded approach to qualitative research. In this entry, *connoisseurship* refers to the act of knowing; criticism refers to representing that knowledge in public venues such as academic books and journals. Founded by Elliot W. Eisner at Stanford University, the educational connoisseurship and criticism model seeks to illuminate the meanings, qualities, and patterns that constitute school experience. While most educational research is informed by the social and behavioral sciences, educational criticism takes its lead from the work of critics in fields such as music, literature, drama, film, and the visual arts. For this reason, educational criticism offers an alternative frame of reference for considering epistemological issues in research. Such issues include the roles of objectivity and subjectivity as well as questions of research validity and generalizability.

This entry is divided into two parts. First, it examines the structure of educational criticism as made up of four overlapping dimensions: description, interpretation, evaluation, and thematic. Second, the entry addresses questions of warrant by focusing on three criteria for assessing criticism. These criteria include consensual validation, structural corroboration, and referential adequacy.

The Structure of Educational Criticism

The first dimension of educational criticism is *description*. This dimension focuses on providing accounts of what critics have seen or heard based on their own firsthand observations. The terms *see* and *hear* are used in this context as achievement verbs. They imply informed discernment and sensibilities. To use an analogy, wine critics do more than enjoy wine. If they are to perform their functions well, they must examine the color and clarity of wine with a trained eye. As connoisseurs, their palates must be able to discern a wine's complex balance and blend of flavors. Critics must attune their sense of smell to the dominant and minor aromas of a wine's bouquet. In addition to wine, one need only consider dance, music, poetry, painting, or sculpture to recognize that such products of human experience are resolutely grounded in sensory perceptions. Likewise, understanding the subtle qualities of a classroom lesson, the nuanced messages of a textbook, or the

dramas of preschool children at play depend on knowing what to look for.

The forms of discernment described above are often associated with fieldwork and data collection. Other sensibilities are involved with the task of providing a vivid representation of what the critic has learned. Description in educational criticism seeks to put others at the scene through expressive language. Such language may employ narrative structures, metaphors, connotative meanings, symbols, and onomatopoeia. Expressive description calls for what some call "an ear for language." In representing the feel of a classroom or the orchestration of a lesson, critics know that matters of tone, tempo, and style make a difference.

The second dimension of educational criticism is *interpretation*. The aim of interpretation is to explicate observations and further an understanding of how and why educational practices take place the way they do. In short, critics not only *sense* the qualities of educational experience, they also seek to *make sense* of them. The contents of observations are interpreted as part of a category, class, or pattern of meaning. Thus, interpretation involves the use of theories and concepts.

All researchers interpret their data using theories that they either bring to a study or develop as the study proceeds. Educational critics, however, do not use theory to predict an experience or its outcome. Rather, theories and concepts are used as maps or guides that help bring into focus certain patterns of meaning. Educational criticism is interpretive in another sense as well. Critics focus their inquiry on how research participants interpret their own experiences. For example, critics might focus on how teachers, students, or school administrators understand a new algebra program, or they might examine what it means to teach under different types of school leadership.

A third dimension of educational criticism is *evaluation*. Evaluation overlaps with both description and interpretation in that these dimensions are shaped by what critics judge to be worth attending to in the first place. On this point, misunderstandings may stem from the lay use of the term *criticism* to mean faultfinding. Educational critics are not so predisposed. If anything, the opposite is true. In the arts, criticism has a tradition of selecting exemplary work to critique. The critic's responsibility is to help others understand what constitutes goodness in domains, like education, that are themselves highly normative. Critics may point to problems, educational or otherwise; but even in these cases, negative evaluations are tempered with an effort to portray the complexities of school practice.

Critics are also quick to recognize that no single value or set of values is agreed on as the final arbitrator of good (or bad) education. Critics may ask how well a lesson promotes critical thinking, is relevant to the students' lives outside of school, fosters cultural literacy, increases equity, or prepare students for adult life. Critics also seek to contextualize their judgments relative to the particular intentions and situations at hand. Here, an analogy with sports may also be helpful. Fans will judge a game based on how well it is played and not simply on its final score.

The fourth dimension of educational criticism is *thematics*. Themes are similar to generalizations in research but significantly differ in their use. Sometimes referred to as transferability, themes represent the recurrent messages, concepts, principles, or patterns that are extracted from the study of particulars. The critic's aim is to recognize and name patterns that will help others better understand experiences they have previously encountered and puzzled over. In this respect, themes contribute to the anticipatory schema that allow interpreting experiences at a more sophisticated level than would otherwise be possible. Even single cases, if they are meaningful, reveal not only themselves but also the qualities and attributes they hold in common with other cases of the same type. Themes are based on this premise.

Issues of Warrant

How does one judge the trustworthiness or believability of an educational criticism? The answer to this question is partly a matter of how criticism is viewed. In particular, critics see research as an amalgam of qualities that are postulated to exist combined with the critic's own sensibilities, beliefs, and values. Because the critic's antecedent knowledge always colors and shapes his or her work, expecting ontological or procedural objectivity is inappropriate. Instead, readers of criticism look for well-supported arguments, reasonable claims, and plausible accounts. Three criteria are useful in making this determination. The first is *consensual validation*. When two or more critics observe in the same school, readers should be able to recognize that particular school or similar schools based on the descriptions provided. This is consensual validation. Educational critics

sometimes share their work with others who are not research participants but who have extensive knowledge in the areas being addressed. If these informed others concur with the criticisms at hand, this is also a form of consensual validation. Yet we look for agreement only in those areas where one would reasonably expect to find it. As noted above, different critics bring different sensibilities informed by different frames of reference to what they observe. Just as a criticism of Shakespeare's *Hamlet* reflects the critic's own reading of that play, an educational criticism reflects the critic's own readings of a classroom, lesson, or textbook.

A second way to assess the trustworthiness of educational criticism is *structural corroboration*. Structural corroboration concerns the weight of the evidence and its rightness of fit. Is the criticism well informed through multiple data sources or by other means? Does the critic provide enough context or "thick" description for readers to reach their own warranted conclusions?

Evidence in all forms of research can be used selectively. For this reason, another aspect of structural corroboration is whether the critic has sought out disconfirming or contradictory evidence. Have critics presented a fair and balanced account of their observations? And have their views changed as a result of their research?

The question of changed views or fresh perspectives is related to a third criterion, that of *referential adequacy*. Referential adequacy is the degree to which the critic's accounts are informative or telling. Two major functions of criticism are to reeducate our perceptions and to enlarge our understandings. Critics seek to accomplish these aims from both a retrospective and prospective point of view. Retrospectively, referentially adequate criticism asks its readers to revisit prior experiences to consider them in a new light. In locating and naming the subject matter of experience, critics often bring into focus aspects of teaching and learning that were otherwise known only tacitly or at a taken-for-granted level. Referential adequacy in this sense allows readers to articulate knowledge of which they had not been fully aware. Prospectively, we can ask about the degree to which criticism serves as a set of cues or guides to understanding future experience. Because no two experiences are identical, all experiences are "new" to the person who undergoes them. Still, many experiences share similarities, and thus, our past shapes how we understand the present and future situations in which we find ourselves. Criticism seeks to further its own foundations of connoisseurship by providing opportunities for learning. On this basis, forms of referential adequacy represent the educational functions and instrumental utilities of criticism.

Continental/Analytic Divide in Philosophy of Education

In the view of many scholars, the Western philosophical tradition, with its long history going back to the days of ancient Greece, ceased to be "a" tradition—that is, a single tradition—shortly after the lifetime of Immanuel Kant (1724–1804). According to this account, about then two different pathways were pursued, each group of philosophers adopting quite different writing and argumentative styles, and each seemingly focusing on different philosophical problems. Furthermore, these two traditions were geographically isolated (at least in the early days), one flourishing on the European continent and the other in the English-speaking world. The two

traditions came to be known as "Continental philosophy" and "analytic philosophy" (or "Anglo-American analytic philosophy"), respectively; and the gulf between them, marked by indifference if not disdain, together with mutual incomprehension, widened with the passage of time. This Continental/analytic divide came to be reflected in the new field of philosophy of education as it evolved during the 20th century. A stereotype of the two traditions caught on; one scholar described it in these terms:

> Precision, conceptual clarity and systematic rigour are the property of analytical philosophy, whilst the continentals indulge in speculative metaphysics or cultural hermeneutics, or, alternatively, depending on one's sympathies, in wool-gathering and bathos. (Stanley Rosen, quoted in Critchley, 2001, p. 34)

The history of the North American Philosophy of Education Society from the late 1950s until the early 1970s bears witness to the existence of this chasm. In the first part of this period, the Society was dominated by individuals who worked within the broad Continental tradition (existentialism was particularly prominent), and analytic philosophers of education were rarely given slots on the programs of the annual conferences—instead, they met clandestinely, "after hours," in the hotel room of some individual who had volunteered to host the reading of a scholarly paper. By the late 1960s and early 1970s, the situation was reversing as seminal work in the analytical mode by R. S. Peters, Paul Hirst, and others in the United Kingdom, and by Israel Scheffler and others in the United States became better understood and more influential. Eventually, analytic philosophy dominated the North American Philosophy of Education Society conference programs; later still, a compromise was reached whereby work from both traditions appeared, a practice that has survived down to the present day (Kaminsky, 1993; Phillips, 2000).

It seems undeniable, then, that there are at least two coexisting modes or traditions; a few moments spent in the relevant section of an academic library will bear this out if further evidence is needed. The problem arises in offering a characterization of the differences between these; the traditional account (a synopsis of which was given above) and the popular stereotype simply do not hold water. In the first place, seeing the divide in geographical terms is quite misleading, for there always have been individuals in the English-speaking world who have pursued philosophy in the so-called Continental mode, and there have been individuals on the Continent who have written and argued in fine analytical style on topics with an analytic flavor. Furthermore, as intercontinental travel and overseas study both became common (together with migration forced on many scholars due to the ravages of war), geographical characterization of the traditions became asinine. Currently, much so-called Continental philosophy (and philosophy of education) is pursued in North America, the United Kingdom, and Australasia, as well as in Europe; and philosophy in the analytic mode can be found in Finland, Sweden, Germany, Austria, and elsewhere on the Continent, as well as in the English-speaking world.

An additional complexity is that some of the roots of English-language analytical philosophy are to be found on the Continent. The German philosopher Gottlob Frege (1848–1925) is often credited with being the father of modern analytic philosophy, and substantial contributions were made by Rudolf Carnap and Ludwig Wittgenstein among others (these two Austrians relocated to the United States and the United Kingdom, respectively); modern philosophy of science owes much—substantively, methodologically, and stylistically—to the logical positivist members of the Vienna Circle and also to Karl Popper (another Austrian)—all of whom moved from Europe to escape Nazi persecution and had an enormous impact on English-language philosophy. Taking note of this history, one authority has suggested that analytic philosophy would be more appropriately identified as Anglo-Austrian than Anglo-American.

The case of John Dewey adds another layer of complexity to the story. It does not seem quite right to characterize him as a Continental philosopher, nor was he an analytic one. He was a towering figure in American (pragmatic) philosophy and also philosophy of education, but he was trained in Hegelian philosophy in the United States (at Johns Hopkins) by professors who had studied in Germany; and his early publications were on Kant and Hegel. However, he also was markedly influenced by William James (a strong opponent of Hegelianism) and by the logician and philosopher of science, Charles S. Peirce. Dewey's influence on philosophers on the Continent has not been trivial, and currently, it is undergoing a new spurt of growth; even some philosophers of education in the United Kingdom read him.

The upshot, then, is that it makes no sense to regard the expression "Continental philosophy" as referring to a place or even to a unified tradition; a distinguished British philosopher and philosopher of education has stated that "the continent, for our purposes, is not a place, but a tendency" (Cooper, 1994, p. 2). The most common tendency pointed out in the literature is the frequent use of high-sounding, vague, unduly complex prose coupled with loosely formulated argumentation—in short, the accusation is that Continental philosophy tends to lack clarity and rigor, in contrast to analytic philosophy, which is clear, straightforward, and logically precise. The analytic philosopher Henry D. Aiken exhibited this tendency when he proclaimed that "reading Heidegger is like trying to swim through wet sand" (quoted in Lucas, 1969, p. 32).

An anecdote involving Karl Popper also is illustrative here. Noted for the straightforwardness and simple elegance of his prose, Popper regarded clarity as perhaps the major virtue of a piece of philosophical (or scientific) writing, for it was associated with openness to criticism and the possibility of error detection (which are important in enabling our ideas to progress toward the truth). On one occasion, when several major Continental philosophers had drawn his ire, Popper wrote this scathing assessment of the intellectual values they passed onto their students—an admiration of "brilliance and impressive opaqueness":

> Many years ago I used to warn my students against the widespread idea that one goes to university in order to learn how to talk, and to write, impressively and incomprehensively. At the time many students came to university with this ridiculous aim in mind, especially in Germany. . . . Thus arose the cult of un-understandability, the cult of impressive and high-sounding language. (Popper, 1976, p. 194)

To put what is perhaps the same point more charitably, it has been suggested that Continental philosophers are more likely than analytic philosophers to write in a literary mode, making use of a variety of literary tropes to make their case. In the 1990s, Jacques Derrida was even accused of producing prose that was full of puns and jokes (and "logical phalluses") and gimmicks akin to those used by the Dadaists—strong condemnation indeed!

However, it is important to recognize that the balance is not completely tipped in favor of analytical philosophy, for it also has had critics. No less a source than *Time* magazine in 1969 ran a story (that could have been written yesterday) on the state of philosophy, in which it was remarked that it had "become a private game for professionals," lacking the social significance it once had possessed. In the past, philosophers had been put to death because of the dangerous significance of their work, but this could no longer happen—not because these days there was more sensitivity about executions, but because "there is no need to kill that which is already dead." The article continued by pointing out that laymen glancing at a recent number of the blue-ribbon *Journal of Philosophy* "would find a brace of learned analysts" discussing which of two logical formulae best expressed the statement "there are brown things and there are cows" (*Time*, reprinted in Lucas, 1969, pp. 29–34). The point was obvious: Analytic philosophy had become sterile (and, strangely enough, this judgment was written about the time there was a groundswell of interest in analytic philosophy of education in the United Kingdom and the United States—for this latter field has always lagged a few years behind its parent discipline).

The difference in focus and in style between the two modes or traditions, touched on earlier, needs to be revisited. Why does work in the Continental tradition use language in such a dense, literary, and (arguably) loose way; and why does analytic philosophy verge on being pedantic in its efforts to be clear and precise? In Simon Critchley's analysis, we need to go back to Kant's philosophy to find the answer. The analytic tradition had its roots in the work of philosophers who focused on Kant's first critique (*Critique of Pure Reason*, 1781). The focus here was to find a grounding for empirical knowledge that avoids the perils of skepticism—essentially, this was an epistemological interest, one that required great linguistic precision and conceptual clarity for its fulfillment in the pursuit of truth. The other tradition (or "culture," as Critchley calls it) stems from Kant's third critique (the *Critique of the Power of Judgment*, 1790); if one takes this route, Critchley (2001) writes, "the burning issue of Kant's philosophy becomes the plausibility of the relation of pure and practical reason, nature and freedom, or the unity of theory and practice" (p. 19). This pursuit—which in essence is the pursuit of practical wisdom and social critique—requires a different set of philosophical skills; it also has been claimed that this focus leads to a greater appreciation of the intellectual history of the relevant ideas.

However, there is an important caveat to enter here; philosophical traditions are not unified, cohesive things, and often internal differences generate more heat than do the external differences with members of alternative traditions. Writing of the Continental tradition, William Schroeder (1999) puts the point this way: "I think that a unilinear model of historical progress in Continental philosophy is misleading and fruitless. But I also believe that the diverse programs in the tradition more often supplement than conflict" (p. 615).

An illustrative example is needed to put flesh onto the bare bones of the preceding discussion. Here, then, are two passages in which "representatives" of each tradition are discussing, in their own typical way, about what is close to being the same centrally important concept. The example is misleading, however, if it suggests that Continentals and analysts were always interested in the same issues; as hinted above, traditions of scholarship tend to have a life of their own, wherein earlier work in the tradition often becomes the focus of vigorous discussion in later work, or is built on by it—the trajectory of a tradition, in other words, is to some extent contingent. (Thus, for instance, the decades-long interest of analytic philosophers of education in the so-called logic and language of education does not run parallel to a similar detailed focus of attention within the Continental tradition.)

For illustrative purposes, then, a good representative of the Continental tradition—one who writes more lucidly than most—is Hans-Georg Gadamer. In 1960, he authored an account (revised in the 1980s) of the concept *Bildung*, which is close to but broader than the English-language concept of education; here is an extended extract:

> In accordance with the frequent transition from becoming to being, Bildung (like the contemporary use of the German word "Formation") describes more the result of the process of becoming than the process itself. The transition is especially clear here because the result of Bildung is not achieved in the manner of a technical construction, but grows out of an inner process of formation and cultivation, and therefore constantly remains in a state of continual Bildung. It is not accidental that in this respect the word Bildung resembles the Greek physis. Like Nature, Bildung has no goals outside itself. (The word and thing Bildungsziel—the goal of cultivation—is to be regarded with the suspicion appropriate to such a secondary kind of Bildung. Bildung as such cannot be a goal, it cannot as such be sought, except in the reflective thematic of the educator.) In having no goals outside itself, the concept of Bildung transcends that of the mere cultivation of given talents, from which concept it is derived. The cultivation of a talent is the development of something that is given, so that practicing and cultivating it is a mere means to an end. Thus the educational content of a grammar book is simply a means and not itself an end. Assimilating it simply improves one's linguistic ability. In Bildung, by contrast, that by which and through which one is formed becomes completely one's own. To some extent everything that is received is absorbed, but in Bildung what is absorbed is not like a means that has lost its function. Rather, in acquired Bildung nothing disappears, but everything is preserved. (Gadamer, 1993, p. 11)

Contrast this with part of the account of the English-language concept of education, written at approximately the same time by perhaps the central figure in so-called ordinary language analytic philosophy of education, the British academic R. S. Peters; there were several parts to his analysis, which was based on his understanding of ordinary English usage:

> (a) The educated man is not one who merely possesses specialized skills. He may possess such specific know-how but he certainly also possesses a considerable body of knowledge together with understanding. He has a developed capacity to reason, to justify his beliefs and conduct. He knows the reason why of things as well as that certain things are the case. This is not a matter of just being knowledgeable; for the understanding of an educated person transforms how he sees things. It makes a difference to the level of life which he enjoys; for he has a backing for his beliefs and conduct and organizes his experience in terms of systematic conceptual schemes. (b) There is the suggestion, too, that his understanding is not narrowly specialized. He not only has breadth of understanding but is also capable of connecting up these different ways of interpreting his experience so that he achieves some kind of cognitive perspective. . . . (c) In contrast, too, to the instrumentality so often associated with specialized knowledge, the educated person is one who is capable, to a certain extent, of doing and knowing things for their own sake. He can delight in what he is doing without always asking the

question "And where is this going to get me?" This applies as much to cooking as it does to chemistry. He can enjoy the company of a friend as well as a concert. And his work is not just a chore to be carried out for cash. He has a sense of standards. (1973, p. 240)

This extended example, though far from perfect, illustrates both the virtues and the drawbacks of the Continental and analytic traditions, cultures, or modes. And it also points to a charitable conclusion, namely, that both approaches probably are useful and that they are to some degree complementary. Both too have their dangers—sterility and scientism on the one hand and (as Critchley concedes) obscurantism on the other.

Cosmopolitanism

Cosmopolitanism is not an easy term to define, given its long conceptual history and shifting contexts. The first known usage of the term is by the Cynic Diogenes in the 4th century BCE. An itinerant from Sinope who lived on the streets of foreign city-states, Diogenes, when asked where he was from, replied, "I am a citizen of the world [*kosmopolites*]." Etymologically, the term is derived from the Greek *kosmos* (universal order) and *polis* (city-state), which together give rise to the notion of a community that is of the world. This emphasis on worldliness and a sense of belonging to a shared community, as opposed to the narrowly construed sense of family, tribe, and nation, has influenced thinkers as diverse as the Roman Stoics, Augustine, and Immanuel Kant.

For Stoics such as Cicero and Seneca, cosmopolitanism was in conversation with the turbulence of imperialism and its multicultural legacy. Here, the shared political community was based on granting citizenship to all human subjects on the basis of their rationality. There is thus a unifying gesture in cosmopolitanism that seeks to bring together cultural differences under a single political umbrella. By the time of early Christianity, Augustine's cosmopolitanism focused instead on an understanding of the unified religious community (the "City of God"), in which diverse individuals were brought together through their universal love of God. In the Renaissance, the great humanist Erasmus professed the idea of tolerance across cultural differences, making a claim for a sense of belonging to a world beyond one's own national or religious interests. Cosmopolitanism received renewed attention in the 18th century in the philosophy of Immanuel Kant, whose work continues to inform much current scholarship on cosmopolitanism across various disciplines, including education. It is important to remember that cosmopolitanism is not merely a Western idea but has also appeared in the ancient scriptures of the Upanishads and Confucius's *Analects* (Hansen, 2011).

Broad definitions of the term abound, and one might also group these various definitions into

political cosmopolitanism, economic cosmopolitanism, cultural cosmopolitanism, and moral cosmopolitanism, each one offering a specialized focus (Kleingeld & Brown, 2006). While all definitions of cosmopolitanism have in common the ideas that we are part of a shared world community and that there is a need for respect of other cultures and traditions, there are very different theories about what cosmopolitanism ought to mean today for political, social, cultural, and educational projects. The wide range of theorizing devoted to cosmopolitanism can be captured by two general orientations: classic cosmopolitanism and new cosmopolitanism.

Classic Cosmopolitanism

Classic cosmopolitanism has emanated primarily from the Stoics in classical times and from Immanuel Kant in modern times. Largely occupying the disciplines of philosophy, political theory, and international relations, most contemporary revivals of cosmopolitanism, however, are indebted to the Kantian tradition as opposed to the Stoic one, with the work of Martha Nussbaum being a notable exception in its combination of the two. Indeed, many have attempted to redefine Kant's early articulations of a world federation, the idea of belonging to a common world, and the fostering of values that cultivate a sense of our shared humanity. Such redefinitions are put in the service of rethinking political institutions and alliances and the moral ground on which such political reforms can take place. This is often accomplished through appeals both to cultural pluralism and to universal principles. In this sense, these renderings deal primarily with political, economic, and moral cosmopolitanism.

For example, two of the most influential theorists have combined elements of present-day liberal democracy with Kantian aspects of cosmopolitanism. David Held (2005) advocates for a "cosmopolitan democracy" based on the realignment of international institutions that would promote democracy globally. Underlying Held's pluralism are familiar Kantian commitments to autonomy and impartial reasoning, which are identified as "metaprinciples" of cosmopolitanism. Nussbaum (1997) argues for a moral understanding of cosmopolitanism, based on our empathic imagination and our capacity for universal reason. Thus, what we share universally forms the moral bedrock for creating a world community that crosses cultural borders. These and other revivals of classic cosmopolitanism base their views on appeals to universal humanity, reason, rights, and world citizenship, taking these (in varying degrees) as fundamental to the project of working toward a more just, harmonious, and peaceful world order.

New Cosmopolitanism

The new cosmopolitanism that emerged in the 1990s can be seen in direct response to the mounting pluralism in societies around the globe, to postcolonialism's emphasis on the importance of this pluralism for founding new movements of social and political thought, and to poststructural accounts of the production of subjectivity not as founded on abstract notions of human nature but as proliferating in encounters with language, discourses, and embodied others. Most often appearing in literary theory and cultural studies, this new cultural cosmopolitanism distances itself from its classic political, economic, and moral cousins. Instead, what motivates these theorists' appeals to cosmopolitanism is a focus on it as a way of life and culture. Thus, although they share with classical forms of cosmopolitanism the idea of transforming society through respect for human differences, new cosmopolitan theories do so less through an appeal to abstract notions of human nature or to metaprinciples of autonomy, impartial reasoning, democracy, or justice and more through radical appeals to the way individuals and groups inhabit and create spaces of cross-cultural exchange.

These theorists often identify cosmopolitanism with cultural hybridity and deracination. There is thus a "loosening up" of the universal terms through which cosmopolitanism is often understood. Malcomson (1998) coins the term *actually existing cosmopolitanisms* as a way of suggesting that it is the lived realities of transnational border crossing—both in terms of movement of populations and in the flow and exchange of ideas—that are the defining features of cosmopolitanisms, in the plural. In addition, the idea that cosmopolitanism itself is differentially experienced and theorized according to one's location in the world acts to frame our political attention. What is evident in the literature, as a result, is a built-in reflexivity about the nature of the term itself: how it shifts its meaning according to the time and location in which it is articulated. Hence, discussing cosmopolitanisms, in the plural, means that the content of the term alters according to whether one is discussing postcolonial Mumbai, Byzantium during the Ottoman Empire,

or present-day New York. Thus, these new theories refuse to see cosmopolitanism merely as a reflection of Western Enlightenment principles. What is highlighted here is not so much a unified ideal but a set of ideas that are deeply contingent on specific times and places.

Education and Cosmopolitanism

Classic cosmopolitanism has to date been more influential than the new cosmopolitanisms in educational circles. Here, the task has been to link cosmopolitanism to ideas of global citizenship, to democratic respect for cultures, and to universal forms of rationality—ideas that are largely based on Kant's understanding of cosmopolitanism. Nussbaum's work along these lines in relation to liberal education has been highly influential in promoting the moral and political aims for education. The focus on cosmopolitan citizenship, in particular, has been identified as a key educational issue in coping with the increasing forms of economic, political, and social globalization. Although these features of Kantian cosmopolitanism have been central to educational research, there are also those who have taken a different tack, relying more heavily on the new cosmopolitanisms without necessarily eschewing outright the classic texts in the field. David Hansen (2011), for one, promotes a "cosmopolitan orientation" to the field of curriculum and to teaching and is mindful of the centrality of the arts and cultural practices in creating a sense of responsiveness to increasingly complex forms of interconnectedness. Other scholars offer critiques of classic cosmopolitanism from the point of view of its difficulty in responding to human plurality in education and in facing the antagonisms that go along with diverse communities and their histories. In light of the continued augmentation of cultural, economic, and political interdependency around the globe, educational researchers of all persuasions will no doubt be drawn to cosmopolitanism's appeal for some time to come.

Cost–Benefit and Cost-Effectiveness Analyses

Both cost–benefit analysis (CBA) and cost-effectiveness analysis (CEA) are used to evaluate programs. CBA is used to compare a program's costs with the dollar value of its benefits. CEA relates the cost of a program to its benefits but does not assign a dollar value to the benefits. This entry discusses how each analysis is performed and details some of the difficulties in estimating and calculating program costs and benefits.

Cost–Benefit Analysis

CBA, also called benefit–cost analysis, is a method used by economists to assess the efficiency of a policy or program. The goal of this type of analysis is to quantify all the impacts of a policy in monetary terms, so that they can be easily compared. If

the benefits more than offset the costs of the policy, the policy is thought to enhance efficiency or social welfare (i.e., the sum of the well-being of everyone in society). In mathematical terms, analysts simply subtract costs from benefits (although some prefer to produce a ratio by dividing benefits by costs). If the outcome of this subtraction is positive, then the policy generates "net benefits," is efficient, and should be implemented: The gains to the "winners" more than offset the losses of the "losers." If the calculation is negative, leading to "net costs," then the policy is inefficient and should not be implemented. Two or more policies may be compared directly by calculating the net benefits/net costs generated by each.

The method sounds very simple, but implementation is much more complicated and controversial. It is not always clear whose benefits/costs should be counted, how to monetize benefits/costs, and whether the estimates are accurate. Although economists continue to research and refine many CBA practices, some common "rules of thumb" have emerged to help guide practitioners. A few of these are highlighted below.

A first step in a CBA is to determine whose costs and benefits should be counted, or who has standing. Ideally, one should count all members of the relevant "society" to appropriately judge social welfare, but it is not clear how to define "society" in the first place. In CBA, economists use a geographic definition, including all parties within a particular country, state, city, neighborhood, school district, and so on. The size of the geographic area will depend on how far the analyst believes that the major impacts will extend. For example, if conducting a CBA of an afterschool program for at-risk youths in one school, the analyst might consider the neighborhood or school district the relevant geographic area, but if the school is heavily financed by state taxpayers or if impacts extend beyond district borders (e.g., graduates will take jobs around the state), one could make the case for a state-level analysis.

Importantly, in a true social or economic CBA, one cannot omit any stakeholders within the geographic area from the calculation, although in reality, analysts often do. In that case, the CBA does not measure efficiency but only measures the impacts on the included groups.

Monetizing Impacts

Quantifying and monetizing the impacts of a policy is the most difficult, time-consuming, and controversial aspect of CBA. Of course, some financial costs/benefits are already in dollars and require little extra in the way of estimation, but many others, particularly in education, are much more difficult to monetize. Ideally, even intangible costs/benefits such as time, a sense of community, increased self-esteem, the value of preserving natural habitats, and so on should be monetized, but sometimes this task is nearly impossible. Again, economists have generated some useful shortcuts for monetizing some of the tougher costs and benefits.

For example, to value time gained or lost due to a policy, economists generally agree that a person's hourly wage should be used. A person's wage reflects not only the value to society (i.e., an employer) of one hour of that person's time but it also reflects the rate at which a person is willing to "sell" an hour of her time—so it is also implicitly the value to her of an hour of time, whether used for work or not. In education research, wages are also used as a measure of the value of attending or completing a certain level of education. For example, if a policy improves high school graduation rates, we would monetize this impact by multiplying the number of additional students graduating due to the policy by the average difference in earnings between high school graduates and dropouts.

Discounting

A CBA can be conducted to analyze impacts of a policy over any number of years. When more than one year of impacts are analyzed, the impacts in each year can be added together. However, before adding them up, the impacts beyond the first year need to be "discounted" to make the dollar values equivalent to those in the first year. The idea is that money (or impacts) in the future are worth less to us. Even in the absence of inflation, we would prefer to have $100 today than to trade it for $100 a year from now. To make that trade appealing, we would need to be paid interest. In CBA, rather than interest rates, we use the "social discount rate" (SDR) to change the dollar values in future years back to their equivalent today. The SDR is the average rate that individuals in society make trade-offs over time. The actual value of the SDR is quite controversial, with analysts using anywhere from 0% to about 9%. Most government agencies require a particular rate to make all their analyses comparable: The average SDR as of this writing is about 3%. A simple formula or the "net present value" (NPV) function in Excel is all that is needed to convert the costs/benefits in the

future back to "present value." When all impacts are in present value, the net benefits/net costs of the policy are now called "net present value."

Sensitivity Analysis

After calculating the NPV of the policy, it would seem from the simple description above that the CBA is done. However, no CBA is complete without some form of sensitivity analysis. At its simplest, a sensitivity analysis can entail changing the most uncertain, largest, or most controversial value(s) in the analysis one at a time, holding all else equal to see if the results change (i.e., if NPV goes from positive to negative, or vice versa). More complicated analyses involve changing multiple values simultaneously and using Monte Carlo methods, a class of computational algorithms that rely on repeated random sampling, among others. A good CBA will carefully explain which values drive the findings and which are the most problematic. The analyst should also discuss any impacts that were left out of the analysis and how they might have changed the results (or not) had they been included.

Cost-Effectiveness Analysis

CEA offers an alternative to CBA that, while much less comprehensive, can be more practical in some situations. Rather than measuring efficiency, CEA does just what it says—it assesses the cost-effectiveness of a policy or program. To do this, the analyst compares all the (discounted) costs of a project (calculated as in CBA) to a single quantified, but *not* monetized, benefit, which serves as a measure of effectiveness. The goal is to divide costs by the effectiveness measure to arrive at a ratio of dollars per unit of effectiveness.

For example, if the main goal of building a bridge is to save commuters time, then the analyst would tally the costs of the bridge (e.g., building, maintenance, etc.) and divide them by the number of commuter hours saved. The "cost-effectiveness ratio" might be something like $20 per commuter hour saved. Now the question becomes whether policymakers should build the bridge. Unlike net costs/net benefits, the cost-effectiveness ratio does not give you a decision rule. Is $20 per commuter hour a good deal or a bad one? For CEA to be helpful in this regard, one must compare it with something else. If a second bridge design has a cost-effectiveness ratio of $10 per commuter hour, then this second design is deemed more cost-effective and should be undertaken instead of the first. CEA is therefore most helpful when there are multiple projects of similar scope under consideration—because it uses a ratio, CEA masks issues of scale—that is, one may generate similar ratios for very large ($100 million/100 million hours = $1/hour) and very small projects ($1 million/1 million hours = $1/hour).

One of the most important issues to consider in CEA is the choice of an effectiveness measure. Because CEA typically uses only one effectiveness measure, all other benefits are ignored. The idea of the effectiveness measure is to measure the outcome that is most indicative of the success of a project. In education, finding a measure of effectiveness may be particularly challenging, since there are often multiple goals of a project (e.g., improved test scores, higher graduation rates, etc.), and they can be difficult to measure. In the case of the after-school program discussed above, the best measure may be the number of dropouts prevented, but this may be hard to evaluate. Instead, one might just use the number of students enrolled in the program. These two measures would yield very different results. To get around this problem, some studies have used combined measures of effectiveness, for example, generating an index calculated from multiple outcome measures as the effectiveness measure. This can be a good solution, but the results can be difficult to interpret, as the ratio becomes dollars per one-unit increase in the index.

Conclusion

In sum, both CBA and CEA can be useful tools in the evaluation of education programs and policies. CBA, while more comprehensive and straightforward, is more time-consuming than CEA. When using either tool, analysts should be careful to explain all assumptions, conduct a sensitivity analysis, and discuss any impacts that have been left out of the analysis.

Creative and Lateral Thinking: Edward de Bono

Edward de Bono is renowned for his criticism of logical, linear, and critical thinking and for his range of thinking techniques to facilitate potential creative abilities that emphasize thinking as a learnable skill and deliberate act. He originated the concepts of lateral thinking (literally sideways thinking) and parallel thinking to distinguish the many techniques for deliberative creative thinking that he has developed from what he considers to be normal perceptions regarding creativity and innovation.

De Bono (1994) draws attention to traditional critical thinking as a judgmental and adversarial process and compares it with parallel thinking, which he claims emphasizes cooperative and coordinated thinking. Critical thinking, he says, has its foundations in a method of philosophizing, known as the Socratic method, first used by the ancient Greek philosopher Socrates and developed further by Plato and Aristotle (whom together de Bono calls the "Gang of Three"). However, his contention is that the Socratic method is focused on discovering the truth and uses adversarial techniques such as refutation of opposition, which rests on is/is not, true/false, either/or dichotomies—a form of argumentation in which contradictory claims are argued to strengthen one side's argument and diminish the opposing position. In practice, each interlocutor takes a different position and points out contradictions to attack the other position in order to prove the other side wrong and, consequently, force a judgment.

De Bono claims that this form of argumentation, which for him is synonymous with the Socratic method, pervades Western thought and that it is "intrinsically fascist in nature" due to its appeal to adversarial thinking. He does not deny a place for the Socratic method but rather argues that it has deep-seated inadequacies no longer able to deal with the kind of radical change that has become a feature of the modern world. It is not so much the search for truth that is required for the increasing complexity of contemporary societies but the development of creative and more effective approaches to problem solving. Subsequently, he introduced the term *parallel thinking* to describe what he considers to be a fundamentally different method of thinking; not only does it reject the adversarial framework in favor of a cooperative model for thinking, but it emphasizes possibility and "designing forward" from the "field of parallel possibilities" by placing claims in parallel instead of in opposition to each other. To use de Bono's preferred terms, useful outcomes are obtained by "design" rather than by "judgment."

De Bono has many formal techniques that can be deliberately applied to teach structured, parallel thinking. His most notable technique, lateral thinking, aims at restructuring thought patterns from which new combinations can arise. De Bono assumes that lateral thinking is the basis of insight and creativity because it is for changing concepts and perceptions and, therefore, is most effective prior to the use of traditional methods of vertical or logical thinking. Its value lies especially in problem solving since it generates alternatives, challenges previously held assumptions, and develops innovative thinking. He argues that thinking can be more effective through direct teaching of thinking as a skill rather than through resisting habitual thinking patterns. In doing so, de Bono makes a distinction between thinking and intelligence and places emphasis on the development of *metacognitive* thinking skills. Accordingly, it is necessary to be conscious of how we think, for new thoughts "can be applied only if one is aware of one's own thinking or thought processes, and understands new thinking techniques" (Burgh, 2005, p. 26).

De Bono has developed formal techniques for deliberate creative thinking, which can be contrasted to coping or reactive thinking strategies. The latter can function only when there is something to react against; it does nothing to produce proposals. Deliberate creative thinking, on the other hand,

focuses attention on what he calls mapmaking—a type of thinking that requires a certain detachment.

De Bono's largest curricular program is the Cognitive Research Trust (CoRT) Thinking Program. It uses strategies, called attention-directing tools or devices for generating ideas, to direct the attention of students to aspects of situations that might have otherwise been neglected before they make decisions. Some of the techniques used in CoRT are as follows: PMI (Plus, Minus, Interesting); CAF (Considering All Factors); C&S (Consequences and Sequel); AGO (Aims, Goals, Objectives); FIP (First Important Priorities); APC (Alternatives, Possibilities, Choices); and OPV (Other Point of View). The main aim of the CoRT thinking lessons is to improve planning and decision making. By employing the attention-directing tools of CoRT, students apply the skill of operacy, a term coined by de Bono to describe action thinking, which he maintains ranks alongside literacy and numeracy.

Another use of attention-directing tools is the Six Thinking Hats that de Bono designed for teaching structured parallel thinking with groups of participants. The Six Hats supposedly represent every basic type of thinking. Each hat has a different color that provides the name for the hat as well as its related function. The white hat suggests neutrality and objectivity. The red hat deals with emotional views, feelings, hunches, and intuitions. The black hat represents the devil's advocate. The yellow hat covers hope and positive thinking. The green hat expresses creativity and new ideas. The blue hat is concerned with thinking about thinking, the organization of the thinking process, and the use of the other hats. Throughout the discussion, hats are used and exchanged, although it is not necessary that people always consciously use one hat or another.

The purpose of the Six Hats is to provide a tangible way of translating intention into performance by simplifying and unscrambling thinking so that the thinker can deal with one mode at a time. It was also designed to allow a switch in modes of thinking by deliberately putting on a particular metaphorical hat depending on which mode of thinking is required. De Bono contends that the artificiality of the thinking hats provides a formality and a convenience for requesting a certain type of thinking either by oneself or by others. Each thinker follows exclusively the mode of thinking indicated by the hat that is being used. The metaphorical use of the thinking hats also establishes rules for the game of thinking, and anyone involved in the game will be aware of these rules. The Six Thinking Hats framework, therefore, provides a process that can be self-monitoring.

De Bono's efforts as an advocate for lateral thinking and creative thinking as an essential skill for creativity and innovation have not gone without criticism. Robert Weisberg, a cognitive psychologist, argues that there is insufficient evidence for the effectiveness of lateral thinking and that the creative process is better described as a process of logical thinking, trial and error, feedback, and reflection. Another criticism is that his description of traditional Western thinking overemphasizes the more extreme forms of adversarial argument apparent in some traditional methods of classroom practice, assuming that all Western philosophical thinking is *necessarily* adversarial. An alternative view of Socrates is that the purpose of his method of philosophical inquiry was to show people how to think for themselves rather than to destroy another person's argument for the sake of proving one's own position. Indeed, other thinking frameworks, such as Philosophy for Children, founded on nonadversarial conceptions of philosophy, also employ the deliberate teaching of skills to encourage creative and divergent thinking. This raises a further criticism of de Bono that while he has been highly successful in gaining the attention of a wide readership, his contributions are not particularly original in substantive content but are restatements of the previously developed concepts of "convergent thinking" and "divergent thinking" without historical or scholarly attention given to key figures in the field of critical thinking and creativity in which he is situated.

Creativity

Over the centuries, philosophers and researchers with different disciplinary backgrounds have debated how creativity is most appropriately conceptualized. There is agreement that fundamentally creativity involves framing new approaches or new questions that enable transition from what is to what might be, and that generation of outcomes (ideas or products) that are considered inherently novel and original are manifestations of creativity. It can also involve framing new questions, generating new ideas, and reflection on both. In this entry, the analysis of creativity that is presented is informed by research in the arts, social sciences, and computational science, and the implications for educational theory and practice are discussed.

Manifestations of creativity can be arranged on a continuum. One end denotes low originality and low impact, or "little-c" creativity (sometimes referred to as "everyday creativity')—for example, generating and enacting an idea that is new to oneself or a small group of others, such as would be involved in making a meal with unusual ingredients, or proposing a change or improvement in a school community. Margaret A. Boden (2004) refers to such novelty at a personal level as psychological and the idea as P-creative. Anna Craft (2001) refers to the same phenomena as "little-c" or personal effectiveness and lifewide resourcefulness, while James Kaufman and Ronald Beghetto (2009) distinguish mini-c creativity (personal meaning making) from everyday creativity or little-c (creativity shared with others), and they introduce "pro-c" (professional) creativity. The other end of the continuum donates high originality and impact, or "big-C" creativity (such as possessed by Gandhi or Einstein); this is what Boden calls "H," or "historical," creativity that changes the world, or that generates novel ideas that transform paradigms.

From the Divine to the Human: Three Psychological Traditions

In premodern perspectives, superhuman force was seen as the source of creativity. For example, Plato referred to the Muses as the source of inspiration for scientists, musicians, artists, and poets. This classical perspective saw the creator as passive and as "receiving" divine inspiration, indeed being "an empty vessel that a divine being filled with inspiration" (Sternberg, 2003, p. 90). This perspective, Sternberg argues, prevented its exploration using scientific methods. By contrast, since the Renaissance humans have been recognized as active agents in creativity (Sawyer, 2006) and since then, the concept has been investigated by researchers. Psychologists were drawn to the study of this human capacity, and they developed a particular focus on what an understanding of creativity can tell us about learning. During the 20th century, three traditions in particular have been influential: cognitive, psychometric, and humanistic.

Cognitive Approaches

Concerned with modeling, the earliest cognitive psychology work was undertaken by Graham Wallas (1926), who identified four phases in the creative process: preparation, incubation, illumination, and verification. Later researchers identified four "dimensions": *product* (creative outcomes), *person* (characteristics or tactics of creative individuals), *process* (habits or patterns), and *persuasion* (impression that convinces others that something is creative). Elizabeth Watson (2007) extended this by adding *place*, recognizing the importance of both environment and culture; and Aaron Kozbelt, Ronald Beghetto, and Mark Runco (2010) introduced *potential*, with an emphasis on learning, recognizing that potentially creative ideas may first emerge as unexpected ideas, which in the context of the classroom may be easily dismissed as off-topic and yet may be signifiers of creative potential.

Some cognitive work focuses on habitual creativity, drawing on both psychology and other related disciplines to explore how habits evolve creatively in dynamic contexts; some research foregrounds tensions between automatic reflex behavior and habitual creativity.

Psychometric Approaches

Efforts to measure degrees of creativity using psychometric methods were begun by Joy Paul Guilford in the 1950s; his work generated interest in tests that could throw light on individual differences. Focused on everyday creativity, offering ease of both administration and scoring together with the opportunity to sample large populations, they proved popular (Sawyer, 2006). Psychometric approaches have been

used to explore creativity, the creative personality or behaviors, characteristics of creative products, and key aspects of environments that successfully foster creativity. The Torrance Tests of Creative Thinking (1974), involving figural and verbal tasks for use with children and adults, are perhaps the most widely used and have been translated into many languages (Baer & Kaufman, 2006). The verbal element contains activities such as unusual uses, unusual questions, ask and guess, and just suppose. The figural element includes tasks focusing on picture completion, picture construction, and repeated figures of circles or lines. The tests prompt responses, which are then scored for their originality, flexibility, fluency, and elaboration together with abstractness of titles and resistance to premature closure. In addition, Hans Jellen and Klaus Urban (1986) developed a test focused only on image production: the Test for Creative Thinking—Drawing Production, which can be used from kindergarten. All these tests have focused on divergent thinking. More recently in France, Todd Lubart, Maud Besançon, and Baptiste Barbot (2011) have developed tests of creative potential, which incorporate both divergent (or exploratory) and convergent (or integrative) thinking designed for use with children aged around 6 to 14 years. These focus, through both the graphic/artistic domain and the verbal/literary domain, on the prediction of creative potential. For divergent thinking, graphic tasks are generating an abstract drawing and generating a concrete drawing, and verbal tasks are creating story beginnings and endings; for convergent thinking, graphic tasks are creating a drawing based on given elements and creating a story based on a title or on characters. The tests, scored by trained judges through an electronic system, generate a creativity profile for each participant.

It has been argued that as well as measuring creativity, these tests can serve as tools to enhance it. On the other hand, the psychometric stance has been criticized for its lack of recognition of the impact of context on "performance," for measuring not creativity but aspects of intelligence, for defining creativity too narrowly, and for correlating weakly with other indicators of creative behavior.

Some psychometric approaches have focused since the mid-20th century on aspects of personality or behavior rather than on the divergent thinking that marks creativity. For example, openness to experience, autonomy, and introversion are emphasized by Gregory Feist (1999); others emphasize risk-taking orientation, tolerance of ambiguity, curiosity, and internal measures of evaluation (e.g., Sawyer, 2006).

Humanistic Approaches

An approach that has its focus on the personal perspective and is concerned with motivation was initiated by Abraham Maslow (1943) and Carl Rogers (1954). Maslow's "hierarchy of needs" modeled how "self-actualized creativity" is only feasible after all basic needs are satisfied, while Rogers's work focused on the role of positive and unconditional regard in developing psychological safety for creative behavior.

From What Is to What Might Be: New Directions

These traditions dominated the early-21st century psychological research. However, as Richard Caselli (2009) argues—drawing from literature spanning neurobiology, psychology, cognitive science, and neuroeconomics—creativity involves bridging the gap between what is (i.e., what already exists) and what should be (the enactment of imagination). This has resonances with Craft's work on "possibility thinking," which emphasizes the transition from *what is* to *what might be* through both "what if?" questions and "as if" behaviors.

Creativity scholars are themselves engaged in transitions to what might be, in the growing recognition of creativity as a social phenomenon having emotional dimensions as well as with motivation, mood, and interaction as key elements. Exploring how high-quality creative ideas are produced is as key an element in much social research as is the ethical dimension. In a world characterized by radical uncertainty, some argue that *wise* creativity (Craft, Gardner, & Claxton, 2008) is necessary, in other words considering the potential impact of creative ideas and actions. Such scholars argue that attending to the impact of ideas on wider communities and contexts is vital to sustained futures; this is referred to as wise, humanizing creativity (Chappell & Craft, 2011; Craft, 2013).

Critical Race Theory

Critical race theory (CRT) is a set of theories that argues that racism is normal, not aberrant, in U.S. life. Legal scholars proposed the notion of CRT after concluding that even their more liberal White colleagues did not fully understand the incredible burden that race put on the people of color, despite advances in civil right rulings and legislation. Many liberal White legal scholars understood that the law and its application were unfair to a variety of people because of their status identities—race, class, gender, sexuality, immigrant status, language use, or ability. Their solution to the built-in inequality of the law was to propose critical legal studies in workshops that analyzed legal scholarship and legal precedence. However, in the midst of one of the workshops, Black legal scholars recognized that even within this alternate space, issues of Black life and experience with the law continued to be marginalized. Realization of this marginalization gave birth to CRT—a place in legal scholarship where race would be central to analysis of inequality.

Early legal scholars in CRT include Derrick Bell (who is widely regarded as the "Father of Critical Race Theory"), Kimberly Crenshaw, Richard Delgado, Patricia Williams, Lani Guinier, Mari Matsuda, Charles Lawrence III, Neil Gotanda, Cheryl Harris, Linda Greene, Gary Peller, Kendall Thomas, John O. Calmore, and others. They argued that, in civil rights law, the traditional approach to addressing inequality through legislation and filing *amicus* briefs was too slow and ineffective to change the social and civil status of African Americans and other non-Whites. Indeed, CRT scholars argued that civil rights laws are never enacted unless those laws also benefit Whites.

On July 2, 1964, President Lyndon B. Johnson signed the Civil Rights Act, the most sweeping civil rights legislation since Reconstruction. The Civil Rights Act bans any discrimination based on race, ethnicity, color, religion, or national origin. On June 4, 1965, President Johnson gave a speech at historically Black Howard University in which he explained that civil rights law alone was not enough to correct inequality, and he provided the underlying rationale for affirmative action:

> You do not wipe away the scars of centuries by saying: "now, you are free to go where you want, do as you desire, and choose the leaders you please." You do not take a man who for years has been hobbled by chains, liberate him, bring him to the starting line of a race, saying, "you are free to compete with all the others," and still justly believe you have been completely fair. . . . This is the next and more profound stage of the battle for civil rights.

> We seek not just freedom but opportunity—not just legal equity but human ability—not just equality as a right and a theory, but equality as a fact and as a result. (Chace, 2011)

On September 24, 1965, President Johnson issued Executive Order 11246, which required government contractors to "take affirmative action" toward prospective minority employees in all aspects of hiring and employment. Contractors must take specific measures to ensure equality in hiring and must document these efforts. On October 13, 1967, the order was amended to cover discrimination on the basis of gender as well.

The inclusion of gender as a part of the federal affirmative action mandate meant that the beneficiaries of the order would now also be White women. Since there are more White women than members of any one group of people of color, the possibility arose that the hard-fought civil rights benefits would now flow into the White community.

The major tenets of CRT include the claim that racism is normal, not aberrant, and constitutive of the fabric of U.S. life and culture, a belief that much of reality is socially constructed, the use of storytelling (or more accurately, counterstorytelling) as a way for marginalized groups to address their marginalization, use of critical social science as a tool for analyzing inequality in the society, and interest convergence as a vehicle for moving civil rights agendas forward.

The belief that racism is normal is a difficult one for most Americans to accept. Given a cultural narrative of never-ending progress and noble purpose, to suggest that racism is both a normal and predictable condition in the nation meets with denial and active resistance. Thus, those who point out the ongoing pattern and systemic nature of racism are discounted as malcontents or "racial opportunists." Critical race theorists identify "microaggressions" that speak to the daily racial indignities that people of color suffer. For instance, common everyday occurrences such as being ignored by a merchant, challenged as to one's ability to pay, or being mistaken as a subordinate reflect the kinds of microaggressions that people of color experience. For CRT scholars, it is the accumulation of these events that is telling rather than the more dramatic or tragic events that occur and gain public attention.

Derrick Bell (1993) codified the "everydayness" of racism by promoting what he termed *the rules of racial standing*:

> 1. No matter what their experience or expertise, blacks' statements involving race are deemed "special pleading."
>
> 2. Not only are blacks' complaints discounted but black victims of racism have less impact as court witnesses than whites.
>
> 3. Few blacks avoid diminishment due to their racial standing.
>
> 4. When a black person or group makes a statement or takes an action that the white community or vocal components thereof deem "outrageous," the latter will actively recruit blacks willing to refute the statement or condemn the action.
>
> 5. True awareness requires an understanding of the Rules of Racial Standing. As an individual's understanding of these rules increases, there will be more and more instances where one can discern their workings. (pp. 111–121)

The notion that much of reality is socially constructed is not a new one; however, the primary research paradigms through which social scientists work suggest that an independent reality is being empirically investigated. Legal scholars know that the work of American jurisprudence is about constructing a reality—to argue a case and a point of view. More pointedly, the very concept of race is a social construction—natural science refutes the existence of race as a viable category, but social science uses it as a primary organizing status category, and sociologists, psychologists, political scientists, and educationists all use it. Thus, the tension between race as a social construct and race as a biological reality forces scholars to deal with the shifting nature of knowledge and to question heretofore "epistemologically verified" notions of the social world.

Storytelling (or counterstorytelling) is an important tool for the CRT scholar. These stories can be fantastical (e.g., see "Space Traders," in Bell, 1993, chap. 9) or realistic, but what they have in common is that they are fictional tales designed to illustrate legal and/or moral dilemmas produced by the way laws, policies, and statutes are developed and implemented. The fantastical storytelling can take on the characteristics of the literary genre known as magical realism, commonly found in the literature of Latin America and described by Schroeder (2004). Challengers to CRT point to storytelling as nonscientific, lacking rigor, and antithetical to the scholarly process.

However, CRT scholars push back with claims that all scholars—especially legal scholars—tell stories, but that those stories may take the form of reports, logs, or descriptions of so-called empirical claims.

CRT scholars employ critical social science as a tool for analyzing racial situations and legal precedence. This means that their work starts from a place where inequity is assumed. That inequity might deal with race, class, gender, sexuality, disability, and so on; scholars such as Pierre Bourdieu (1986), Michel Foucault (2002), Nancy Fraser (2003), Paulo Freire (1970), or Antonio Gramsci (2011) can be instructive in providing an alternative vision of the social world—one that assumes the existence of inequality and the need to address it.

Another primary tenet of CRT is an acceptance of the interest convergence principle. This notion was used by Bell (1980) to argue that Black social, economic, and civil concerns will be addressed only when they intersect or converge with those of Whites. Thus, even among our most cherished civil rights laws, CRT scholars uncover the way these laws also serve White interests. For example, the landmark *Brown v. Board of Education* (1954) decision is touted as one of the Supreme Court's finest moments. The ruling that "separate is inherently unequal" seemed on the surface to be solely a commitment to racial equality. Bell (1980) and later Mary Dudziak (1995) argued that despite the seeming civil rights meaning of the decision, actually it also served as a foreign policy move during the Cold War to signal to nonaligned states that the United States provided fair and equal treatment under the law to its Black citizens. However, more than 50 years past *Brown*, the majority of Black and Brown children attend deeply segregated schools. Even in those places where school desegregation was attempted, we see retrenchment from the law.

CRT is approximately 20 years old and is exploding into a variety of areas beyond law, such as sociology, education, anthropology, economics, cultural studies, and other fields. In the July 2011 issue of the *Connecticut Law Review*, Crenshaw (2011) explores the viral-like spread of CRT in many other fields. The work challenges scholars to consider the way race continues to matter even in a society that wants to identify itself as either "colorblind" or "postracial." In 1995, Ladson-Billings and William F. Tate introduced CRT into education research and theorizing. By analyzing education inequity through the lens of CRT, they argued that race still matters; that the United States is a nation built on property rights, not human rights; and that the intersection of race and property provides a powerful rubric for making sense of ongoing inequality in U.S. schools. Ladson-Billings and Tate used CRT to analyze school funding, assignment to special education, discipline practices, curriculum as a form of property, and testing and assessment.

Critical Theory

The term *critical theory* (CT) was coined by Max Horkheimer (1895–1973) in 1937 to describe a politically committed response—grounded in the German philosophical tradition of Immanuel Kant, Friedrich Hegel, and Karl Marx—to the problems of modernity and, in particular, to the catastrophic events and social changes of the first half of the 20th century. CT aims to achieve the emancipation and transformation of individuals and society through human action. Theory and practice form a single process, and philosophy is put to work to provide an analysis and critique of society, leading to social change. The political significance of the action of educating is brought to the fore, and education takes a central place as a means of promoting individual autonomy and addressing issues of prejudice and authoritarianism. CT also has relevance to the nature of education research as an interdisciplinary intellectual enterprise that seeks to negotiate the relationship of theoretical research with empirical methodologies.

CT has shifted through a number of distinguishable phases since 1923, when the first generation of Marxist social theorists formed the Institute for Social Research affiliated with Frankfurt University. The principal members of what came to be known much later as the Frankfurt school were Max Horkheimer, Theodor Adorno (1903–1969), and Herbert Marcuse (1898–1979). Many others were associated with the school, including the literary critic and philosopher Walter Benjamin (1892–1940), the psychologist Erich Fromm (1900–1980), and the sociologist Friedrich Pollock (1894–1970). Most prominent among the second-generation critical theorists is Jürgen Habermas (1929–), whose theory of communicative action attracts continuing interest in education theory seeking to understand the role of schools in developing democratic values and practice. *Critical pedagogy*, a term coined in 1983 by Henry Giroux (1943–), has its origins in CT and describes educational praxis (theoretically informed practice that has an emancipatory and egalitarian premise).

First Generation: The Frankfurt School

The Marxist orientation of the Frankfurt school theorists led them to expect the end of capitalism as its own internal logic unfolded. The Russian Revolution of 1917 had briefly seemed to confirm the correctness of this prediction, but by the time of the founding of the institute, Russia had undergone years of civil conflict, with ruinous consequences, and the violent suppression of German communists under the nonrevolutionary moderate socialism of the Weimar Republic confounded the revolutionary hopes of the political left there. Accepting neither Moscow nor Weimar, the institute returned to the philosophical roots of Marxian theory. The members of the school were deeply affected by the rise of Nazism and spent much of the next two decades in exile, mainly in the United States where they found sanctuary in American universities. Perhaps the greatest personal and intellectual tragedy for the school during this period was the death by suicide of Benjamin in France in 1940.

CT defines itself in terms of liberation from circumstances that enslave; the purpose of philosophy is to make a significant difference to human life, including its material conditions. This transformation is to be achieved through analysis and critique, which leads to a desire for change. However, what confidence the members of the school shared that human happiness and well-being might be increased was strictly circumscribed by what they believed to be ever-tightening limitations on autonomous activity. Constraints on human freedom that were formerly theological and feudal seemed increasingly to shape intellectual activity by way of certain insidious social changes. Immediate historical circumstances also shaped CT: As the Great Depression was followed by 16 years of increasing political and social chaos in Europe, feelings of absolute loss caused the members of the Frankfurt school to abandon, to a great extent, what had only ever been a cautious optimism about human happiness.

Against this background, nonetheless, the school never entirely lost its faith in the transformative power of education. In his lecture "Education after Auschwitz" (1966), Adorno argues that, in view of the monstrous events that took place, all education should have the end of fostering critical self-reflection and self-determination and of countering the barbarous and violent tendencies of authoritarianism and the exaggerated attachment to technological thinking and to collective identity. In "Taboos on the Teaching Vocation" (1969), he outlines how this ambition for education stands in sharp contrast to the way in which schools can represent an authoritarian, hierarchical, and frequently violent, prototype for fascism. Education for autonomy, Adorno

recognizes, is constantly at risk of misrepresentation and attack; children's capability for independent thinking may be damaged at a very early age, and yet democracy depends on it.

The radical student movement of the 1960s turned to the Frankfurt Institute for inspiration and support and pirated copies of the members' earlier works circulated widely. Marcuse willingly became the intellectual mentor of the student leaders with a number of articles that established his position as the voice of the new left; and Habermas, the relative newcomer to the institute, addressed student conferences and spoke to student leaders in Germany. However, with the exception of Marcuse, the relation of the members of the institute to the student activists was rather fraught and complex. Aspects of their writings resonated strongly with the students' revolutionary aspirations and mood, but in the end, the students wanted something that CT could not give them—an uncritical endorsement of their actions and ambitions. It is important to understand that, in spite of its Marxist origins and its emphasis on praxis, CT is not an ideology but an open-ended methodology in which the contradictions and omissions of a particular social world are explored from within to reveal other possibilities and new ways of being. This is *immanent criticism*, which can be understood in contradistinction to an ideological critique based on fixed and transcendent principles.

The activity of exposing the omissions and contradictions between the principles and practice of a given society has meant that CT is frequently described as negative. The refusal to propose an alternative way of organizing society should be understood not as a result of a sour negativity or quietistic abnegation but, rather, as the result of a steadfast commitment to human freedom. The abuse of ideologies during these decades adequately explains the critical theorists' cautious reticence about constructing the future; but it is also a result of a deeper understanding of the role of philosophy as interpretive and explanatory. Hegel's "Owl of Minerva," that spreads its wings at dusk, signifies the task of philosophy, which is the intellectual apprehension of mature reality—at the end of the day, as it were, rather than before it dawns. For the critical theorists, philosophy has a formative role in the maturation of reality, but it is, and should be, backward looking. An important strand of CT is the philosophy of history, particularly as it features in the work of Benjamin, who combined an account of childish and of historical consciousness to formulate a distinctive, somewhat idiosyncratic, theory of hope and historical redemption.

The idea that critique must be grounded in, or immanent in, a particular system or society raises the specter of relativism. The realization that societies are plural and complex means that appeal to the idea of community can result in an unnerving loss of certainty. Aversion to dogmatism and utopian theory seems to entail that we give up any objective or transcendent normative basis for critique, except for the rather second-rate version of normativity provided by each particular group or society. However, the caution exercised by the members of the Frankfurt school with regard to transcendent normativity—that is, to a standard for judgment that comes from a system or theory unrelated to the world as it is—not only reflects their historical context but also has its roots in the understanding they shared of the relation between the universal concept or theory and the particular circumstance or experience. Truth does not reside in one or the other but in the dynamic relation of the two. The imposition of the universal over the particular denies the reality of experience or forces that reality to conform to an idea; the assertion of the particular over the universal, on the other hand, results in chaotic activity without direction or purpose. CT gives priority or finality to neither theory nor lived experience. Truth is liable to change, but this does not mean that it is an illusion. This is a distinctly Hegelian insight that truth is transitory and incomplete, that each concept is "sublated" by a subsequent one. The result of this is caution and humility rather than relativism or the abnegation of responsibility for present suffering.

This appeal to public discourse as a source of normativity can be interpreted as falling squarely within the Enlightenment tradition wherein truth flows out of the rational activity of autonomous individuals who are given free voice and where their opinions are open to public critique. The idea that reason needs the checks and balances of public discussion to transcend the merely subjective is one way in which community may be understood as a source of normativity.

Interdisciplinary Method

The immanent criticism favored by the critical theorists, then, situates critique within life as it is—within the practices, traditions, values, and beliefs of a particular society; and though it is not constrained by these circumstances and can postulate

ways in which things could be otherwise, it holds to the principle that critique ought not to be detached. However, CT also steadfastly rejects positivism in social research, because of the way in which it misrepresents social phenomena as "givens," and sees theoretical research as pure, neutral, self-substantive, and ahistorical. Horkheimer describes this empirical bias as resulting in the *reification* of social facts, which is inherently conservative rather than transformative or revolutionary, and is the foundation of the view that the purpose of knowledge and inquiry is the domination of nature.

The tension between the empirical and theoretical approaches to social research became a very present reality to critical theorists working in the context of American universities, where social research was almost exclusively empirical and pragmatic. In addition to the desire to combine the two social research traditions on theoretical grounds, they faced a pressing practical necessity to work with their American colleagues. The most important piece of research to emerge from this exigency was *The Authoritarian Personality*, first published in 1950, an extensive study of prejudice that drew on psycho-scientific methodologies to refine and support the formulation of ethical and political commitments.

Second Generation: Habermas and Communicative Action

Habermas is recognized as one of the most important social theorists of the postwar era. His work is prolific and interdisciplinary and owes much to his early participation in the Frankfurt school, where he worked as research assistant to Adorno from 1956 (though the direct association was relatively short lived). Habermas has written little that is explicitly on the topic of education, but his ideas have been highly significant for educational discussions of democracy, participation, and citizenship and for the development of action research as an educational methodology.

Habermas's contention that knowledge is not neutral but socially constructed, and that what counts as worthwhile knowledge needs to be interrogated to discover the particular interests that are served by it—what he calls "knowledge-constitutive interests"—has been particularly influential in critical pedagogy and reflects the emancipatory commitments of CT. He takes a critical view of the hegemony of the empirical-scientific model of knowledge, for which he uses the term *cognitive-instrumental rationality*, and contrasts it with another aspect of reason, which he calls *communicative action/reason*, which is the mode that has often been used by people in everyday situations to reach understanding and agreement and to coordinate their actions. This idea of communicative reason is given full articulation in his 1981 work *The Theory of Communicative Action*. As with the approach of his CT predecessors, this was not an outright rejection of scientific methodology but a reconfiguration of it in the context of a broader, more comprehensive concept of reason. Habermas's argument is that the suppression of communicative reason in the modern era has allowed technocratic approaches to dominate all aspects of life without the rudder of political and ethical deliberation, resulting in the technologically enabled atrocities of the 20th century that have mortally wounded modern faith in progress.

Communicative action is the mode of the *public sphere*, a concept that Habermas derives from Hannah Arendt's *space of appearance*, and which he first develops in *The Structural Transformation of the Public Sphere*, published in 1962. The public sphere is envisioned as an inclusive space for rational-critical deliberation between free and equal individuals committed to reaching an agreement on matters of common concern and common good. Habermas traces the genesis of the public sphere to 18th-century Europe and the beginnings of Enlightenment thought and argues that in the rediscovery of the norms of the public sphere can be found a defense of modernity's "unfinished project" and a counter to the dystopian analysis of modernity found, for example, in Adorno and Horkheimer's *Dialectic of Enlightenment*, first published in 1944. In communicative action, in the structure of discourse itself, Habermas looked for the source of normativity that would give a positive impetus to critique. The evident fact that when we voluntarily enter into a discourse, we do so on the assumption that agreement is possible may be further interrogated to reveal the standards and rules inherent in communication itself.

Like John Dewey, Habermas focused on the essential importance of deliberative communication to healthy democracy. Democracy is not simply a matter of extending participation. The erosion of the function of the public sphere has come about in a number of ways, none of which necessarily entails reduced participation, for example, low levels of educational attainment, control of information by commercial interests, and the debasement

of public opinion to an aggregation of preferences. Communicative action requires freedom from all such constraints and coercion that would compel participants to reach a false consensus. It is how decisions are arrived at and opinions formed that determines the validity of democratic decision making. The idea of communicative reason has distinct implications for education since there is a need to develop in children the competencies that enable participation in a pluralist public sphere through a pedagogical emphasis on discussion, negotiation, and collaboration. What this might mean for the development of deliberative democracy in an educational context has been further explored by writers such as Seyla Benhabib, Iris Marion Young, and Amy Gutmann. One criticism of Habermas's theory of democratic deliberation hangs on the suggestion that he fails sufficiently to recognize that asymmetric power is inscribed in the situation itself. This is an important consideration for children's participation in discourse where it seems that it is sometimes thought that inequality can be "good-willed" away. Similarly, Habermas's apparent equation of discourse and argumentation might serve to exclude certain groups, notably young children, whose mode of communication is not rational-logical or even linguistic. The question generally remains as to how the gap between our ideal and actual situations may be bridged.

Action Research and Ideology Critique

Action research plays an important role in teacher education, but the term itself has a number of different meanings. In Habermasian thought, it relates to the notion of *ideology critique*, an element in Marxist social theory that has as its aim the exposure of injustice. In his 1972 work *Knowledge and Human Interests*, Habermas outlines a process of inquiry that entails the hermeneutic investigation of a situation, a critique of that interpretation to identify the blatant or covert knowledge-constitutive interests, followed by a decision about how the situation may be altered to achieve greater equality, and, finally, an evaluation of the effectiveness of the action taken. This four-stage process may readily be applied to critical interventions in pedagogical situations, which reflect the teacher's commitment to education on the basis of equality and universal entitlement. Other forms of action research may be concerned solely with improving the technical aspects of teaching without reference to ethical-political considerations, an interpretation that is at odds with the fundamental tenets of CT.

Conclusion

The continuing relevance of first-generation CT in educational theory and practice lies in the recovery of utopianism to drive and direct what educators do, without anticipating a particular future state. This is a difficult and delicate, intellectually open, middle way between the twin horns of the "efficiency agenda," which is shaped solely by a desire to measure and improve education as a process aimed at attaining a set of known goals (familiar to teachers in terms of talk of accountability and effectiveness), and the alternative, the imposition of an ideologically driven agenda for change. Such a conception of teaching as a politically significant, countercultural activity is consistent with constructivist theories of learning that give central importance to the fostering of critical self-reflection. Habermas's theory of communicative action focuses our attention on the way in which educational ends are determined, as well as on who participates in this discourse. His thinking also effectively mounts a direct challenge to the educational research community to engage in the immanent critique of its own privileges, knowledge-constitutive interests, and engagement with sociopolitical issues of pressing concern.

Critical Thinking

The invention of critical thinking often is attributed to the early Greeks, especially to Socrates, some 2,500 years ago. Wherever it began, critical thinking properly is called an invention, as noted by the important 20th-century philosopher of science, Sir Karl Popper. Its emergence in the human species was not inevitable. It found a catalyst in the Socratic method, an approach to solving problems that relies on posing a series of questions the answers to which result in solutions to the problems. Thus, critical thinking can be thought of as an intellectual technology—an artifact designed to accomplish certain ends.

The critical examination of proposed solutions to problems often is hailed as the method of all rational discussion. The idea of criticism is not meant to be one of finding fault—in the sense intended, a person offering criticism might provide either a positive or a negative assessment. The key is that the criticism is accompanied by reasons, which point, in the case of negative criticism, to possible routes to improvement.

Critical thinking finds a natural home in education, because it has been equated to rationality. As such, critical thinking is central to education for several reasons. One reason related to the growth of knowledge, both in society and in individuals, is that critical thinking is the basis of the academic disciplines on which education places special emphasis. A moral reason for critical thinking is that dealing rationally with others—that is, dealing with them on the basis of reasons—is a key way of showing respect for those others, including students. When thought of in this manner, critical thinking must play a major role in formulating educational goals and in designing educational interventions.

This entry deals first with early and later formulations of the concept of critical thinking; second, with two major controversies that occupy much of the debate within the field, both dealing with different aspects of the generality of critical thinking; third, with the relationship between critical thinking and a cognate area of study, informal logic, that resides primarily within philosophy departments; and, finally, with attempts to reach consensus on the meaning of critical thinking.

Early Formulations

The earliest uses of the term *critical thinking* in the 20th century were outside of the context of elementary and secondary (K–12) education. Critical thinking was associated closely with logic and with postsecondary education, as one can find in the work of Max Black. With such affiliations to logic, the concept of critical thinking referred to generalized standards and principles of reasoning on which reasons for judgments could be based. According to this view, reasons require generalized standards and principles as their basis, else they cannot serve as reasons. Consider an example. A person wishes to defend the continued exploration and exploitation of hydrocarbon resources and offers as a reason that the economy would suffer otherwise. When asked about why the economy matters, the person might respond that a suffering economy would lead to greater unemployment and more widespread pain and deprivation and that human pain and deprivation are to be avoided. The latter claim, that human pain and deprivation are to be avoided, is an example of a generalized standard to which one can appeal in order to support a very wide variety of other claims, including the one here about hydrocarbons. Lacking an acceptable generalized claim such as this one, the claim about hydrocarbons would appear arbitrary and as serving a narrow interest.

Critical thinking was brought into the K–12 educational context in the late 1950s by B. Othanel Smith and in the early 1960s by a seminal article authored by Robert Ennis. The focus continued to be on correctly assessing statements, which was proposed as the central meaning of critical thinking. The attention to statement assessment kept critical thinking tied very much to truth seeking and to the formation of belief—not in the sense of faith or trust but in the sense of conviction based on reasons and evidence.

Later Formulations

Critical thinking attracted considerable academic attention in the final two decades of the 20th century. During this period of active philosophical debate, three notable advances were made in the conception of critical thinking that have become widely accepted by the most prominent theorists in

the field. The ideas marking these advances already were nascent in the earlier formulations, but it took concerted attention to the meaning of critical thinking to render them more clearly and to bring them to widespread attention.

The first advance was the growing recognition that critical thinking must be focused not only on what to believe but also on what to do. This shift in focus meant that critical thinking must be directed to finding both what is true and what is right. Critical thinking would remain thinking based on generalized principles and standards, but these principles and standards would have to be expanded to include ones applicable to the moral and ethical domain, the touchstone disciplines for the study of right action.

The second advance was the realization that critical thinking must be directed toward the self as much as it is toward others. That is, it is necessary for critical thinkers to be fair-minded by assessing what they have said and done in addition to what others have said and done. Yet more than this is required. In making assessments of what others have said and done, critical thinkers must turn their critical thinking on their own assessments to guard against biases and unjustified assumptions that may have skewed these. It is incumbent on the critical thinker to be self-aware and to attempt as much as possible to eliminate or compensate for threats to fairness in judgment.

The third advance was to stress that critical thinking arises from a certain sort of character. The implication of this thought is that it is not enough to teach students *how* to think critically and to expect them to be critical thinkers. In addition to the knowledge of principles and standards, and to the skills of credibility assessment, making inferences, and analyzing arguments, students need to acquire critical thinking dispositions (such as fair-mindedness mentioned above) and the disposition to think critically when it is appropriate to do so. The fostering of dispositions is quite a different matter from the teaching of knowledge and skills. A person might have all the knowledge and skills needed to be a critical thinker, yet he or she may choose not to think critically or choose not to do so as frequently as appropriate.

The upshot of these three advances is that by the turn of the 21st century, critical thinking was not simply another educational goal with academic consequences, such as educating for better-thinking scientists. Teaching critical thinking was seen as an effort to instill character. In the first instance, critical thinkers were to focus on making decisions that lead to right actions—that is, on actions that can be justified by sound moral and ethical reasoning. Second, critical thinkers must focus on their own thoughts and hold themselves to the same standards of critical thinking to which they hold others. Third, critical thinkers must be fair- and open-minded individuals who base their decisions about what to believe and do on reasoned reflection. So, in addition to a manner of thinking, critical thinking had been elevated to a moral stance that educational systems should adopt and to which teachers and students should be encouraged to aspire.

Subject Specificity

One of the most heated debates about critical thinking concerns its generality. The debate has been framed in at least three ways. First, there is the question of whether critical thinking taught in one domain of knowledge or subject area will transfer in use to other areas. The doubters have said that little transfer occurs and can be expected to occur, so there is little reason to attempt to teach critical thinking in general. Critical thinking should be taught in the context of each subject. Some, however, have argued that at least the most general logical principles transfer from one subject to another, and perhaps other principles transfer as well, such as those used to assess the credibility of sources or to discern the structure of an argument. Moreover, some involved in the debates have argued that critical thinking dispositions, such as open- and fair-mindedness and the disposition to think critically when appropriate, are fully transferable from one domain to another. Still another group maintains that considerable conceptual clarification about the distinction between domains and subject areas is needed before empirical research can yield any answers to the question of critical thinking generality understood in this sense. Where, for example, does biology end and chemistry begin? If you think there is a clear line between these subjects, then what is to be made of the subject of biochemistry? Yet, unless a clear line can be drawn, what sense can be made of the claim that critical thinking taught in the context of biology will not transfer to thinking critically in chemistry?

Second, there is the question of whether the principles and standards of critical thinking vary from subject to subject. There is a group of theorists who have argued that critical thinking simply is different in, for example, physics than it is in history. According to this group, there is nothing to transfer

from one subject to another—critical thinking must be taught in the context of each subject because it is manifested differently in each one. Critics of this view respond much as they do the first position. They maintain that the same general logical principles apply in history as they do in physics; that judging the credibility of a source of information relies on the same principles and standards in history as it does in physics; and that being open and fair minded are the same dispositions in each field. Finally, there are those who point out the vagueness in the distinction between subjects. If you wish to maintain that the principles and standards of critical thinking are different from subject to subject, what do you say about a subject like biomechanical engineering housed in a medical school? You need to be able to distinguish that subject from biology, from engineering, and from medicine.

Third, there is the claim made most prominent by John McPeck that because critical thinking is always thinking about something, there is no sense in talking of critical thinking in general. Because no sense can be made of critical thinking in general, critical thinking in general cannot be taught. This argument has been rejected widely because it fails to demonstrate a link between the two propositions. Several analogous cases have been proposed where the connection does not hold. For example, although bike riding is always riding some bike in particular, that does not mean there is no bike riding ability in general. The defender of the view needs to show that even though the connection does not hold in the bike-riding example, it still does hold in the critical thinking example because the examples are not analogous. No defender has successfully made this case.

Critical and Creative Thinking

Another challenge to the generality of critical thinking is that it leaves out an important form of thought—creative thinking. Theorists of creative thinking have tended to reject this characterization. On the one hand, it is a documented fact that inventions, scientific discoveries, and artistic performances—all undeniably creative achievements—require the exercise of critical judgment in their execution. On the other hand, critical thinking typically requires imagining alternatives and likely outcomes and devising approaches to problems—once more, all undeniably creative achievements. Thus, it is broadly recognized that critical thinking plays an essential role in creative thinking and that creativity is at the heart of thinking critically.

Critical Thinking and Informal Logic

There are two other fields of study, informal logic and argumentation, that are aligned closely with the study of critical thinking. The second of these is associated primarily with the field of linguistics and will not be discussed further in this entry. The first, informal logic, finds its home in philosophy departments and has fostered a link with philosophers of education. Informal logic began in part as an alternative to formal logic, which of course is an important part of the philosophy curriculum in colleges and universities. The issue was that formal logic does not help an individual deal with everyday problems, framed in everyday language, that nevertheless require systematic thought—or at least, formal logic does not provide such help clearly or directly. Informal logic grew as an attempt to provide such systematization. The primary focus of informal logic is on arguments (i.e., lines of reasoning offered to support conclusions)—how to analyze their structure, how to identify implicit statements in them, how to assess them, and how to counter them. As such, informal logic is closely related to critical thinking, but it differs in having a narrower focus. Nevertheless, the areas of study are closely allied.

A Consensus Meaning

It is sensible to ask whether consensus exists on the meaning of critical thinking. About two decades ago, the American Philosophical Association sponsored a study that attempted to answer this question. The research employed a Delphi method, which involved a panel of experts participating in several rounds of discussion aimed at achieving consensus on answers to a series of questions. (The consensus was understood as a majority judgment, not a unanimous one.) The characterization of critical thinking as consisting in skills and dispositions was supported by the report. Although not explicit on the question of the generality of critical thinking, the entire tone and mode of expression of the report implied clearly that critical thinking was thought to be generalizable to all or most subjects and problems requiring good thinking. Close affinity with creative thinking was acknowledged but not explored beyond that. Long lists of critical thinking skills and subskills and dispositions were provided, and consensus was claimed

about these. However, given the research method employed and the argumentative nature of the field, it is perhaps wise to place less trust in the claimed consensus on the specifics than on generalities such as the two named earlier in this paragraph.

Cultural Literacy and Core Knowledge/Skills

Cultural literacy is shorthand for a defined body of shared knowledge, skills, and sensibilities that reflect the values, attitudes, and tastes of a dominant culture. Proponents of cultural literacy argue that if all members of a community can activate a common reference system, they will be able to communicate more successfully with one another, be more effective political participants, prevent grievous repetitions of history, avoid reinventing the wheel, and foster humanistic ideals through exposure to the best, most beautiful, and intelligent works of mankind. Altogether, cultural literacy is seen as laying the essential groundwork for advanced education and critical thinking. This conception of the humanistic and cultural benefits of general education is a legacy of the 19th-century British poet and thinker Matthew Arnold. This entry discusses the potential benefits of cultural literacy, concerns about what facts and ideas are emphasized, and the controversy over the common core movement in the United States.

The debate over cultural literacy was a touchstone of the culture wars that took place during the 1980s and 1990s, and this entry will outline the major positions advanced on both sides of the issue. The publication of E. D. Hirsch's book *Cultural Literacy* in 1987, followed one year later by his *Dictionary of Cultural Literacy*, ignited a furious controversy over the benefits and demerits of holding all students to a prescribed canon of knowledge and making them study approved sets of great works. A large number of detractors of cultural literacy, mostly from academia, questioned the usefulness and legitimacy of this approach and condemned the motives and effects of the method. They advocated instead a more contingent, flexible, skills-oriented, and child-centered curriculum.

Those who oppose the idea of cultural literacy object to the kinds of value judgments that proponents of cultural literacy habitually make: Galileo Galilei and Virginia Woolf are more important than Giambattista Vico and Violet Hunt. The gulag is more important than the Battle of Alcatraz. Heisenberg's uncertainty principle is more important than the Heisman Trophy. As with any list, cultural-literacy primers are open to attack on matters of inclusion and exclusion. But supporters of cultural literacy insist that to aspire to the highest standards of excellence, value judgments are ultimately inevitable, even if they are unpopular in certain quarters and are labeled elitist or ethnocentric. At the same time, advocates of cultural literacy such as Diane Ravitch and William Bennett acknowledge that setting precedents of importance and canons of excellence does not mean avoiding metacritical debates over the rationale involved in making these judgments. Nor does it mean that the cultural productions of "lesser" or nondominant cultural formations do not deserve close study and sustained attention if they are deemed important in their own right. It does mean, however, that cultural

literacy fosters loyalty to a cultural formation deemed dominant.

Attacks against cultural literacy that characterize it as popularizing an ossified curriculum can be blunted by reference to the history of American general education. What is considered essential "core" knowledge has changed over time—from the study of classical languages and rhetoric in colonial times, to the Great Books approach of the mid-20th century, to the emphasis on information literacy today. One thing has remained despite all of these changes: Cultural literacy places a premium on memory. It is deemed essential that certain facts of history (including the history of art, literature, and ideas) are kept alive from generation to generation to generate a sense of continuity and to foster an expanding store of cumulative knowledge. Ravitch argues that this knowledge base, far from inhibiting critical thinking is, in fact, its crucial precondition.

Critics of the idea of cultural literacy, including Stanley Aronowitz, Henry Giroux, and Peter McLaren, have argued that it is an exclusionary, ethnocentric, and reactionary strategy aimed at maintaining the socioeconomic status quo. Not only were defenders of cultural literacy seen as old-fashioned information mongers, but they were also condemned as elitist gatekeepers of privilege, creating an atmosphere of stifling conformity. The go-to authority of such views was the Brazilian education theorist Paulo Freire, whose 1970 essay on the "banking concept of education" (first published in *Pedagogy of the Oppressed*, 1970) associated the idea of inculcating a shared body of common knowledge with the dehumanization of learners, who are transformed into passive receptacles of data. Against this banking concept, Freire proposed a problem-solving type of learning that is attuned to local knowledge, involves dialogue between teacher and student, and aims at change rather than stasis.

By contrast, American proponents of cultural literacy maintain that a common core of knowledge and skills, including knowledge of the Bible, world literature, world history, politics, geography, economics, technology, math, and Standard English, is the currency needed to participate in the marketplace of ideas. According to this line of argument, the conversations conducted by those in power have been shaped by (mostly private) elite schooling, which puts a strong emphasis on core learning. Elite preparatory schools such as Phillips Academy in Andover, Massachusetts; Roxbury Latin School, also in Massachusetts; and the Lawrenceville School in New Jersey provide the bases of a liberal arts education encapsulated in phrases such as "solid grounding in the fundamentals," "core curriculum," or even "Homer and Virgil." The types of conversations that the graduates of these elite schools initiate on college campuses, in board rooms, at political meetings, or during cocktail parties cannot be joined by those who lack a sufficiently sophisticated reference system, thus relegating them to the margins.

The college classroom is a particularly instructive laboratory for testing the viability of cultural literacy. Those who cannot spell properly, who write (and speak) nonstandard English, whose vocabulary is limited, whose historical knowledge is sketchy, whose sense of geography is skewed, and whose literary and artistic reference system is thin are often unable to join the conversations held in college classrooms and tend to drop out in frustration. Or they may not gain admission to their dream college in the first place. As the growing socioeconomic imbalance at elite colleges shows, applicants from schools that promote solid core knowledge outperform those from institutions with less emphasis on rigorous core curricula. Of course, factors other than school curricula also affect educational outcomes and admission to elite colleges, as children from prosperous households enjoy a plethora of advantages over their less privileged peers, ranging from a menu of enrichment activities to often more stable family structures. Still, cultural literacy can be viewed as a way to even the playing field rather than as an insurmountable obstacle for those hailing from less affluent environments.

Opposition to cultural literacy is energized by what some see as the specter of a national curriculum. In the United States, Congress has instituted considerable barriers to implementing a national curriculum. Even the "Common Core Standards," adopted by President Obama's Department of Education, have been attacked as possibly unconstitutional. Although these Common Core Standards are de facto voluntary, because states can opt to implement them, the fact that such adoption is linked with funds via the "Race to the Top" (a policy created by the U.S. Department of Education to spur innovation and reforms in state and local district K–12 education) makes them vulnerable to the charge of introducing a national curriculum through the back door. At the time of this writing, 46 states and the District of Columbia have effectively adopted the Common Core Standards developed by the National Governors Association

Center for Best Practices in collaboration with the Council of Chief State School Officers. In substance, these standards outline the foundational skills and appropriate levels of analytical rigor with which subjects in mathematics and English-language arts are to be taught at any given age. Whatever lists of texts are provided should not be deemed prescriptive but merely illustrative of the complexity, quality, and range of materials that should be taught. The suggested literary texts reflect significant racial, ethnic, national, gender, class, and age diversity, thus alleviating concerns about modeling a restrictive and lopsided canon. In all, the Common Core Standards prioritize a skill-based vision over a content-based vision of cultural literacy, and they are thus miles apart from the more prescriptive vision of cultural literacy advanced by Hirsch.

While the test-based approach of the No Child Left Behind law has been almost universally acknowledged as a fiasco, critics who aver that the Common Core Standards will further entrench mediocrity are making speculative judgments. Most European education systems are based on a national curriculum, although differences between individual nations exist. These national curricula lay out in more or less detail a common core of subjects and skills that should be covered in all schools. Critics of the American Common Core Standards movement would need to answer why a national curriculum is undesirable if nations like the Netherlands, Finland, and South Korea—which do feature a national curriculum—produce students who habitually outperform their American counterparts in reading, math, and science literacy (Organisation for Economic Co-operation and Development, 2009).

Opponents of cultural literacy often invoke the "lists" of cultural-literacy proponents as the principal damning evidence to disqualify the whole project. They reasonably contend that lists are not equivalent to learning. But the initiator of the cultural-literacy debate, Hirsch, himself, emphasizes that the lists of learning objectives specify merely desired (or prescribed) outcomes regardless of the specific pedagogic techniques used to reach these objectives; they are not formulas to be memorized for their own sake. Hirsch distinguishes between an extensive and an intensive curriculum. While the extensive curriculum leans more heavily on factual learning and list-driven learning, the intensive curriculum leaves much room for flexible approaches. With this two-pronged approach, Hirsch is aiming to balance compulsory broad coverage with optional in-depth learning that allows for individual and local choice. Again, such an approach almost exactly mirrors the academic philosophy of the elite private schools in the United States.

Even those who are in favor of strengthening the teaching of cultural literacy are not claiming that it is the alpha and omega of education. Rather, they see it as the building of a solid, versatile foundation. Real in-depth learning, critical thinking, and problem solving can only be established on the basis of this quintessential body of information and skills. In this sense, cultural literacy is not an end in itself but a sophisticated tool set.

Curriculum, Construction and Evaluation of

While education can take place without teachers, administrators, or school buildings, a curriculum is required in any educational scheme, for a curriculum is a plan of action that sets out learning activities about some subject. Since instructional time is limited, decisions must be made whether to include topic *x* or topic *y*; curriculum constructors make these decisions, explicitly or tacitly, based on educational purposes that act as filters to determine what to include. Curriculum construction also involves questions about how to design or organize the content of the curriculum since everything cannot be taught at once. How questions of purpose and design, which are interrelated, are answered is consequential since these two factors direct teaching and learning in some ways rather than others. Curriculum evaluation is the process of gathering and using information about a curriculum, usually to improve it or judge its effectiveness. This entry discusses the way in which decisions are made about curriculum construction, changes in the approach to curriculum construction since the late 1800s, and different approaches to curriculum evaluation.

The Scale and Timing of Curriculum Construction

Curriculum construction normally occurs as a result of a policy decision. These types of policies are broad statements about the subject with which a curriculum will deal and the purposes it is intended to accomplish. Policy decisions are made by authorities at a variety of levels, including national and international as well as regional and community levels. Policy sets boundaries within which curricula are constructed.

Curriculum constructors interpret policy and develop specific plans and materials for students and teachers to use. These plans and materials can range from skeletal outlines of content to instructional scripts. A curriculum may be generic or made for a more restricted population. A generic construction is intended for any student or teacher of a given description, and it is typically constructed at a distance from where it will be used. Examples include state- or provincial-level curricula and curriculum packages intended for dissemination across large areas. Local curriculum construction is more likely to be targeted to the identified needs of a specific population of students and teachers. Local construction more likely involves the cooperation of potential users of the curriculum than does generic construction.

Generally, curriculum construction is regarded as an activity occurring in advance that formulates activities and identifies materials used in instruction. As Philip Jackson observed, there is a significant distinction between this "pre-active" sense of curriculum and "interactive" curriculum, which is an outcome of the interactions among instructional materials, teachers, and students. In an interactive sense, curriculum is at least partially constructed in use. This could manifest itself in a number of ways. John Dewey (1998) noted two of them. First, the effects of "collateral learning" from classroom routines may inculcate enduring habits and attitudes that are just as important as the formally stated objectives of a lesson. Second, he endorsed the participation of the student in forming the purposes of what is studied. Twentieth-century examples of interactive curriculum include the project method developed by William Heard Kilpatrick in the United States and open classrooms in the Plowden-oriented primary schools of England—primary schools of England influenced by a 1967 parliamentary report, headed by Lady Bridget Plowden, that promoted student-centered learning.

Approaches to Curriculum Construction

As Herbert Kliebard (2002) has documented, the modern sense of curriculum as an objectives-driven planned sequence of learning activities only emerged in the United States toward the close of the 19th century. In the 1890s, the first national committees were formed to determine what should be taught in the burgeoning public schools. Although these committees broke new ground, they conformed to tradition by retaining school subjects as the building blocks of the curriculum—although, to be sure, the "modern" subjects were not necessarily the same subjects or in the same form as those in the classical curriculum.

This conception of the curriculum reflected the significant role played by subject specialists from colleges and universities in the committees. Much of the resultant curricula mimicked the subject organization of the college curriculum. Although sometimes challenged as a curricular form of organization, its champions, such as Mortimer Adler, have argued for subjects as the basis for curriculum construction down to the present day.

By the early 20th century, however, the hold of college- and university-based subject specialists in curriculum policy and construction was challenged. More heterogeneous groups claimed a voice in curriculum, as did the first self-styled curriculum specialists. A prominent example of the former is the National Education Association, which convened a commission on secondary education, producing a report, *Cardinal Principles of Secondary Education*. The commission began its deliberations by considering the aims of secondary education in a democratic society, which did not necessarily devalue the role of school subjects but nor did it automatically afford them a pride of place.

Progressive scholars and professionals in the United States during the early 20th century placed great faith in science and efficiency. Thus, it is scarcely surprising that this faith found its way into the thinking of the newly minted profession of curriculum specialist. Perhaps more remarkable is the extent to which the assumptions of the so-called scientific curriculum construction have remained widely accepted into the 21st century. One of the major branches of scientific curriculum making found inspiration in studies of efficiency conducted in industry. Leading proponents of this view—the view that curriculum should be based on efficiency—such as Franklin Bobbitt and W. W. Charters, did not question that schools existed to serve the purposes of the existing social order; later in the century, neo-Marxist social critics and others, such as Michael Apple, were to go somewhat further and claim that school curricula served the purposes of the ruling class in a society. Bobbitt, however, argued conservatively that curriculum construction should begin with activity analysis. That is, curriculum makers should survey the activities—both occupational and leisure oriented—that children would have to perform as adults. This would provide a supposedly impartial scientific basis, since the social needs and activities were "discovered" rather than being the mere preferences of some authority for constructing objectives and learning activities. In this approach, traditional academic subjects were valued only insofar as they contributed to the demands of future living. Although sharing the faith in science of the times, Dewey held a different conception of science. He strongly argued that Bobbitt's emphasis on preparing for the future was misplaced. Dewey insisted that the only way a curriculum could prepare students for the unknown future was by fully engaging them in the demands of present living.

Not all scientific curriculum constructors had the intrinsically conservative purposes of the Bobbitt-Charters approach. For example, Harold O. Rugg marched with the times in his embrace of scientific curriculum making, but he saw curricula as being devoted to the cause of social reconstruction rather than social adaptation. Rugg constructed curricula focused on identifying and finding solutions to problems of society.

Perhaps the most famous approach to curriculum construction was presented by Ralph W. Tyler in 1949. It became known as the "Tyler rationale." In earlier years, Tyler had worked as an evaluator of a variety of curricula. This possibly accounts for his conceiving the curriculum constructor's task as more about identifying the questions *any* curriculum constructor must answer than providing his own answers to those questions. Tyler's starting point was identifying objectives. Rather than creating the objectives, Tyler said they could be obtained from sources such as the nature of the learners, the demands of life outside of school, and subject specialists. This was supposed to avoid the danger of curriculum constructors imposing their own values through determining objectives. Critics such as Kliebard note, however, that specifying which sources should be looked to as a source of objectives was itself an imposition of values. Moreover, Tyler's scheme bears more than a passing resemblance to Bobbitt's "discovering" educational needs.

One of the major conclusions of research since the 1960s is that the implementation of a curriculum, which is not always considered a part of "construction," may be as important in determining what actually is enacted in classrooms as the materials developed in advance.

Curriculum Evaluation

Authorities and other stakeholders often want information about a curriculum: What happens to this plan of action, and what effects does it have? Often student performance is taken to be the main, even

sole, index of a curriculum's effectiveness. As Elliot Eisner (2002) points out, this approach omits other potentially significant factors that may affect how the program turns out, such as the quality of its design, the clarity of its objectives, and its suitability for a given audience. Below are some of the major issues in curriculum evaluation.

In 1967, Michael Scriven famously suggested that one way of thinking about methods of evaluation is to distinguish between "formative" and "summative" modes. That is, formative evaluation is intended to provide feedback to a program (either while it is under development or when it is complete); the purpose is to provide guidance about making improvements. Summative evaluation, on the other hand, is intended to provide an overall assessment of the program (possibly because a decision is imminent about whether to continue using the curriculum or adopt a new one). A chef tasting a dish while cooking it is doing a formative evaluation; a restaurant critic sampling it is doing a summative evaluation.

Evaluators sometimes disagree on what yardstick to use to judge the effectiveness of a program. Often a program's performance is compared with its previously determined goals. One problem with this approach is that curricula, for reasons already touched on, change during their enactment, possibly creating potential for outcomes not envisaged by the setters of the original goals. With this in mind, Scriven argued that evaluators should be most concerned with the effects of a program rather than being preoccupied with whether it met its initial goals.

Evaluation would also seem to invite comparisons among programs, seeking the most effective of them. This is a sensible-sounding aspiration. But it turns out to be difficult to accomplish. As Lee Cronbach (1963) pointed out, the variation within one group studying the same curriculum is frequently greater than effects attributable to one curriculum versus another.

Dalton Plan

The American teacher Helen Parkhurst (1886–1973) developed, at the beginning of the 20th century, the Dalton Plan to reform the then current pedagogics and the then usual manner of classroom management. She wanted to do away with teacher-centered lockstep teaching. The Dalton Plan was based on the idea that students learn best by organizing their schoolwork themselves and freely cooperating with their teacher and fellow students. This entry discusses how Parkhurst developed the Dalton Plan, the principles of the plan, and the growth of Dalton education.

During her first experiment, which she implemented in a small elementary school as a young teacher in 1904, she noticed that when students are given freedom for self-direction and self-pacing and to help one another, their motivation increases considerably and they learn more. In a later experiment in 1911 and 1912, Parkhurst reorganized the education in a large school for 9- to 14-year-olds. Instead of each grade, each subject was appointed its own teacher and allotted its own classroom. The subject teachers made assignments: They converted the subject matter for each grade into learning assignments. In this way, learning became the students' own work; they could carry out their work independently, work at their own pace, and plan their work themselves. The classrooms were turned into laboratories, furnished and equipped as work spaces, and tailored to meet the requirements of specific subjects—a place where students work. Useful and attractive learning materials, instruments, and reference books were put within the students' reach. The benches were replaced by large tables to facilitate cooperation and group instruction. This second experiment formed the basis for the next experiments, at the Dalton School and other schools in New York, from 1919 onward. The only addition was the use of graphs and charts enabling students to keep track of their own progress in each subject. From that time on, it was called the Dalton Plan.

In 1921 and 1922, Parkhurst explained the theory of the Dalton Plan in a series of articles published in the *Times (London) Educational Supplement* and in her book *Education on the Dalton Plan.* It can be reconstructed as follows. According to Parkhurst (1922), the Dalton Plan is an "efficiency measure": "a simple and economic reorganization of the school" (p. 46). Lockstep teaching is not efficient, because it is the teacher who does all the work. The Dalton Plan "creates conditions which enable . . . the learner to learn" (p. 34). Learning is the same as experience: "Experience is the best and indeed the only real teacher" (p. 152). The school has to provide for sufficient experience. This cannot be achieved by keeping students as passive recipients, separating them from one another, holding them in one place, requiring them to remain silent, making them learn lessons by heart, and subjecting them to whole-class recitation. We can provide for experience through the "liberation of the pupil" and the "socialization of the school" (p. 46).

In the Dalton Plan, freedom is the opportunity to do the schoolwork oneself, to organize it oneself (how, where, and when), and to carry it out at one's

own pace, particularly to do it undisturbed and to work with commitment and concentration. Self-activity brings about experience. Something similar applies in the Dalton Plan to interaction and cooperation. When students are permitted to interact and work freely with one another and with teachers, in varying groups, in varied locations, with varied resources and materials, they come into contact with one another, the teachers, the subject matter, and the learning materials in different ways. This means more experience and, consequently, more learning.

In the 1920s and 1930s, Dalton education spread throughout the world. It is difficult to determine the exact number of Dalton schools, but there was Dalton education in America, Australia, England, Germany, the Netherlands, the Soviet Union, India, China, and Japan. Particularly in the Netherlands, China, and Japan, Dalton education has remained in existence. In recent years, there has been a revival of international interest. It crops up again, for instance, in England, Germany, the Czech Republic, and Slovakia. The Netherlands is the country with the highest density of Dalton schools. As of 2013, there were 400 Dalton schools in the Netherlands, most of them elementary schools. Making up 5% of all elementary schools, Dalton education is by far the largest educational reform movement in the Netherlands. And, contrary to Montessori, Jena Plan, and Waldorf education, it is steadily on the increase. The only Dalton school in the United States is the school that Helen Parkhurst herself founded in 1919, and was subsequently to direct for more than 20 years: the Dalton School in New York. It is a renowned school. But today, its fame is not due to its origins as an experiment in progressive education: The Dalton School is one of the most expensive private schools in New York.

Daoism

Daoism (Taoism) is an ancient philosophy with origins in texts written in China more than 2,500 years ago. For perhaps just as many years, Daoism has also been practiced as a nontheistic religion, at times in secret when other philosophical/religious groups were in political and cultural favor. The key Daoist writings are characterized by many paradoxes, poetic language, and contradictory messages. Some writings ask many questions but do not provide answers, or they may answer with another question, which can be confusing to readers used to straightforward prose. In spite of its perplexing qualities, Daoism has been advocated and popularized throughout the millennia as holding truths about the pathway (*dao*) to take in life as well as the way (*dao*) to do things. Thousands of volumes have been published about Daoism, including several hundred translations into dozens of languages and interpretations by scholars and historians over two millennia. Along with the Bible, the ancient *Daodejing* (Tao Te Ching) is one of the most published books on earth.

Daoism does not hold a reputation for being an "educational" philosophy; it does not advocate formal education. Indeed, its writings have even aimed criticisms and poked fun at Confucianism, one of the most influential and powerful educational philosophies in China. However, Daoist precepts do advocate seeking wisdom in natural, informal ways. Also, given that the educational decisions of teachers and students are influenced by their personal belief systems, Daoist values have been a

potential influence on goals, curricula, instructional techniques, and student expectations.

Foundational Texts of Classical, Philosophical Daoism

As with many other major philosophical and religious traditions in the world, Daoism has grown from its beginnings in storied places with legendary scholars who were believed to have produced seminal writings. However, as the philosophy spread to other cultures and times, the original texts were altered and embellished with new interpretations and applications. Variant spellings of names arose, and religious practices that embraced the local customs of adoptive groups emerged. Discoveries of historians, archaeologists, and anthropologists came to support the notion that writings regarded as those of single individuals were actually the work of multiple authors.

The *Daodejing* and the *Zhuangzi* (Chuang Tzu) are referred to over and over as the most important sourcebooks for Daoist thought. At the end of the 6th century BCE, these volumes were said to have been created by individuals named Laozi (Lao Tzu) and Chuang Tzu (Zhuangzi).

Laozi, known as "The Old Master," was a sage during the late Zhou (Chou) Dynasty. He decided to leave his position as archivist in the court, disgusted with the corruption of the princes, the unrest of the warring states, and the general discord in society. According to tradition, the gatekeeper begged him to write down his thoughts before he traveled into the wilderness, so before he left, riding on the back of a water buffalo, he jotted down 81 short chapters of the volume we know as the *Daodejing*. On interpretation, its poetic sayings and proverbs offered wise insights and practical precepts. Some ideas are repeated many times throughout the chapters, with layers of meaning added by the varied contexts. For example, the importance of putting yourself low is presented as the valley spirit, the female, the root of heaven and earth, the follower, the one below, and employers who serve their workers. Being flexible is presented in imagery of water, with qualities of being both yielding and strong, but it is also shown as bamboo, able to bend but extremely strong, and as the precept that yielding is better than coerciveness in leadership. A reader of Laozi's writings comes away seeing the importance of practicing stillness and peace, simplicity, constancy, naturalness, taking the middle road, and being calm, as well as avoiding tendencies such as pride, extravagance, desire, striving, and "overdoing."

The volume titled *Zhuangzi* was created at about the same time as the *Daodejing*, but it came from a different region within China. Its stories share encounters and dialogues between fictional characters, both humans and animals, along with parables and admonitions, all organized and synthesized over time from dozens of chapters into the current seven divisions. Ultimate meanings highlight principles such as equality (of individuals), relativity (i.e., the value of any event varies with its context), freedom (from worldly things, from conventions), knowledge (the importance of great experiences), humanity (the importance of interactions, communication), and virtue (character development).

In the years before 1000 BCE, other writings were known to promote philosophical insights that were later emphasized in both the *Daodejing* and the *Zhuangzi*. One particularly influential text was the *Yijing* (I Ching), also known as the *Book of Changes*. It was known for its early presentation of the concept of *yin* (the receptive principle) and *yang* (the creative principle) as opposites that interact in dynamic ways to promote change. *Yin/yang* dualities are part of the dynamic balance within nature, such as hot/cold, male/female, mountains/valleys, or day/night.

Daoist Concepts

Many precepts associated with Daoism overlap with one another, while others may seem to be at odds with one another and are elusive to logical explanation. Beyond the important concept of *yin* and *yang*, some other ideas significant to Daoism include the following:

De (te) is the term that accompanies *Dao* in the title *Daodejing*, which can be translated as *The Way and Its Power*. It represents the vitality of an individual who gains harmony with the rhythms of nature. Fulfillment comes through inner strength, not through trappings such as the acquisition of riches.

Wuwei (wu-wei) indicates the action of practicing nonaction. Although it is quite a paradox, it can be thought of as doing things as part of the ebb and flow of nature (as in going with the flow). *Wuwei* means being spontaneous and comfortable with life and not indulging in competitiveness and aggression.

Pu (p'u) refers to the state of untouched simplicity that would characterize an uncarved block of wood before it is altered. It indicates the ability to

experience life in natural and spontaneous ways before being affected by the prejudices and dualistic, right/wrong thinking of living in the world.

The *three jewels of the Tao* are compassion, moderation, and humility. These three attributes characterize someone in the *Dao*. Showing love for others, avoiding doing things to excess, and not bragging are advocated attributes.

Applied and Religious Daoism

Early on, perhaps in the 3rd century BCE, the influences of early Daoist thought spread through multiple texts and the impulses of growing numbers of people to create a philosophy of life. The focus on health, personal spirituality, longevity, and immortality meant that people turned to breathing exercises, meditation, retreats into nature, herbal remedies and recommendations for physical development through yoga, *taiji* (t'ai chi), and intricate sexual practices. Religious Daoism also came to include ceremonies, priests, alchemy, evocation of spirits, and fortune-telling. Although many, including Westerners, thought of Daoist religious practices as divergent from the original philosophical vein, others involved in philosophical analysis during the late 20th century tended to see the holistic thinking and body involvement as important and worth examining.

Comparisons of Daoism With Other Philosophies

Daoist philosophy has long been revered, right along with Confucianism and Chan (Zen) Buddhism, as a mainstay of Chinese philosophy. Indeed, individuals throughout China easily hold all three philosophies within their personal belief systems. The views of each frequently conflict with one another, but there are also many overlapping, supportive elements. Citizens of modern China also include practitioners of Christianity or Islam.

To compare and contrast all the philosophies is beyond the scope of this entry, but a look at Daoism in contrast to Confucianism would certainly serve as a way to further define Daoist belief. The descriptors below recur in the literature:

Daoism	*Confucianism*
Individuality	Group goals
Harmony with nature	Planning, structure
Assistance, mentorship	Directed instruction
Peacefulness, tranquility	Social activism
Relativism (depends on viewpoint)	Black or white
Flexibility, tolerance	Single path, rules
Intuition	Logic
Political equality	Political hierarchies
Pluralism	Oneness
Skepticism	Solid belief
Acceptance, stoicism	Assertion
Wisdom of following	Aggressive leadership
Female emphasis, equality	Male dominance
Harmony of all living things	Human superiority

In analyzing the attributes of modern classrooms and education movements during the past century, recent scholars have drawn convincing parallels between Daoism and the qualities of progressive, holistic, and constructivist education. Modern observers of school practices know that teachers and school programs often attempt to help students find inner calm, peaceful attitudes, and personal fitness in a world beset with stressful political events and natural disasters and times of escalating social and technological change. However, it is very Daoist *not* to label these approaches as Daoist, for the first passage in the *Daodejing* reminds us that the way is nameless. Individuals may indeed adopt multiple philosophies. What will be will be.

Deconstruction

The word *deconstruction*, which was introduced into philosophical discussion by the Algerian-born philosopher Jacques Derrida (1930–2004), is today often used as shorthand for the critical reading of texts and the critical analysis of philosophical ideas and arguments. While much of Derrida's work does indeed contain critical readings of the work of other philosophers, and of philosophical concepts and ideas more generally, and while such readings do focus on underlying assumptions, including metaphysical assumptions, the word *deconstruction* actually has a much more precise and much more original meaning in Derrida's work. The aim of this entry is to clarify what the idea of deconstruction is "about" and to show how, through this, Derrida has made a highly original contribution to the philosophical discussion, one with important implications for education.

The Metaphysics of Presence

A major argument in Derrida's work has to do with his observation that the history of Western philosophy can be read as an ongoing attempt to identify a foundation that serves both as an absolute beginning and as a center from which everything emanating from it can be mastered and controlled. Derrida has argued that ever since Plato such an origin has been defined in terms of *presence*, that is, as an origin that is fully self-sufficient and fully present to itself. Here, we should not only think of such apparent foundations as "God" or "nature" but also of such phenomena as "consciousness," "the brain," "interaction," or "communication." Any attempt to present something as original, fundamental, and self-sufficient is a case of what Derrida refers to as the *metaphysics of presence*. According to Derrida, the metaphysics of presence not only is about the identification of something as original and self-sufficient but also entails a hierarchy in which what is seen as original and fundamental is depicted as pure, simple, normal, standard, and self-sufficient, so that everything that emanates from it can only be understood in terms of derivation, complication, deterioration, accident, and so on.

Metaphysics-in-Deconstruction

Why might the metaphysics of presence be a problem? One answer Derrida has given is that for something to be present, it actually always requires the "help" of something that is *not* present, that is, of something that is *absent*. *Good*, for example, only has meaning because it is different from *evil*. One may wish to argue that good is originary—that is, primary and fundamental—and that evil is secondary and therefore has to be understood as a lapse or a fall from goodness. But as soon as we try to define good without any recourse to the idea of evil, it becomes clear that the presence of good is actually only possible—that good can only be present—because of its relationship to what it is not, that is, its relationship to evil. We could say, therefore, that the idea of good is contaminated by the idea of evil. But this contamination is not accidental but is actually essential for "good" to have any meaning at all. This shows, however, that the very "thing" that makes good possible at the same time undermines it and makes it impossible. In more philosophical terms, we could say—and this is indeed how Derrida has formulated it—that the condition of possibility of presence is at the same time its condition of *im*possibility. And it is this strange "logic" where the condition of possibility of something is at the very same time its condition of *im*possibility that Derrida refers to with the word *deconstruction*.

Looking at it this way shows that deconstruction is not something that Derrida does or that other philosophers can do after him. It is, in other words, not some kind of method that can be applied. Deconstruction is rather something that *occurs*. While it is not up to us to let deconstruction happen or prevent it from happening, what we can do—and this is something Derrida has done many times in his own work, for example, in relation to notions such as "writing," "democracy," "friendship," and the "gift"—is to reveal the occurrence of deconstruction or, to be more precise, to reveal the occurrence of *metaphysics-in-deconstruction*.

Deconstruction Is Justice

Why might this be important? The most straightforward answer is that we might point at cases of metaphysics-in-deconstruction to do justice to what is absent and invisible but yet is necessary for something to be present. It is to do justice to what is excluded from what is present but is nonetheless necessary for what is present to be present. It is about challenging the authority of the "is," as Derrida has put it, the authority of presence—and in this sense, revealing metaphysics-in-deconstruction can be seen as a critical "gesture." More positively, it is about doing justice to the "other of presence"—which is

one of the main reasons why Derrida has suggested that deconstruction actually *is* justice.

This makes it clear that, unlike what many people seem to assume, Derrida's philosophy—which is sometimes itself referred to as *deconstruction* or *deconstructionism*—is not negative or destructive but rather *affirmative*. It is affirmative of what is absent from what is present but yet makes this presence possible. Derrida's philosophy thus seeks to open up the metaphysics of presence—or for that matter any system that presents itself as self-sufficient—in terms of what cannot be thought of in terms of the system and yet makes the system possible. This means that the point of revealing metaphysics-in-deconstruction is not simply to affirm what is *known* to be excluded. It rather is an affirmation of what Derrida refers to as something that is "wholly other," of something that is unforeseeable from the present. Revealing metaphysics-in-deconstruction thus entails an openness toward an *unforeseeable* in-coming of what is other. In some places, Derrida refers to this as "the impossible," bearing in mind that "the impossible" is not about what is *not* possible but about what cannot be *foreseen* as a possibility.

Beyond Foundationalism and Antifoundationalism

All this does not amount to a destruction of metaphysics. While Derrida questions the possibility of pure, self-sufficient foundations, he stresses that this does not mean that we can simply do away with them, for the simple reason that to be antifoundational, we already need to stand somewhere. Although Derrida wants to "shake" metaphysics—and in this regard his philosophical work clearly has a critical impetus—he acknowledges that this cannot be done from some neutral and innocent place "outside" of metaphysics. What is more to the point, therefore, is that Derrida wants to "shake" metaphysics by showing that metaphysics is itself always already "shaking," that it is always already "in deconstruction." In this regard, his "project" is different from those forms of critical philosophy that position themselves outside of what they want to be critical of or that simply declare that we should abandon the whole idea of foundations.

Education-in-Deconstruction, Deconstruction-in-Education

Derrida's work has suffered from quite a lot of bad press, particularly from those who saw it as destructive rather than affirmative—who saw it as a destruction of certainties rather than as an affirmation of the exclusions that make such "certainties" possible. Nevertheless, educational theorists and philosophers have tried not only to show the ways in which deconstruction can be said to occur in education but also to highlight why it might be important to make this visible. One important line of work has focused on the role of communication in education. While communication is often depicted as the transportation of information from one location to another, *human* communication is a process that takes place through interpretation. We can say, therefore, that it is only because students try to make sense of what their teachers teach that education is possible. This reveals, however, that what makes education *possible*—interpretation—at the very same time makes it *impossible*, as interpretation is a radically open process where the identity between what is said by the teacher and how it is interpreted by the student can never be completely guaranteed. Why might it be relevant to highlight the deconstructive character of educational communication? Not to suggest that education is not possible at all—which would be a destructive conclusion—but rather to appreciate what would happen if education were to become 100% possible, so to speak—that is, when education would turn into a process of the "perfect" transmission of information from teacher to student. To achieve this would require that we suppress all interpretation; it would require that we turn our students from human subjects into abstract, inhuman objects. While some believe that this is all that education should be about, many would argue that this turns education into indoctrination and would thus lead to the end of education. This is an important reason why we need deconstruction in education.

Deliberative Democracy

Deliberative democracy is a growing branch of democratic theory that is very influential in contemporary political practice. Deliberative democrats suggest understanding democracy in terms of exchange of reasons rather than voting or aggregation of preferences. Deliberation involves a process of mutual justification where participants offer reasons for their positions, listen to the views of others, and reconsider their preferences in light of new information and arguments. However, deliberative democracy is not a unified theory; different versions of this approach exist.

The roots of deliberative democracy can be traced back to Aristotle and his notion of politics; however, the German philosopher Jürgen Habermas's work on communicative rationality and the public sphere is often identified as a major work in this area. This entry first focuses on the theoretical underpinnings of deliberative democracy and identifies its different strands. It then describes how this theory has been applied in practice, noting its role in civic education; and finally, it presents the various criticisms that have been leveled against it.

Legitimacy

Deliberative democracy has been developed as a response to the legitimation problems of representative democracies. Although deliberative democrats differ in the extent of their criticism of representative democracy, they often conceive their view not as an alternative to liberal representative democracy but as an expansion of it. This means that while traditional tools of decision making (majoritarian voting, elections, and legislatures) remain essential, the public deliberation of free and equal citizens becomes central in legitimating collective decisions. As Joshua Cohen puts it, on this account democratic legitimacy is understood in terms of the "right, capacity and opportunity" for those affected by collective decisions to participate in the making of those decisions. Other deliberative democrats define the conditions required for achieving democratic legitimacy differently. While procedural theorists locate the source of democratic legitimacy in the presence of fair rules of the process, substantive theorists focus on the fairness of the final outcome.

Schools of Thought

Deliberative democrats differ on the questions of what sorts of communications count as deliberative, where deliberation should occur, who should deliberate, and what should be the outcome of such participation. There are no doubt continuities among these scholars, yet they operate ultimately with divergent fundamental assumptions and see different processes at work when they emphasize the need to make democracies more deliberative. It is common to distinguish between the Rawlsian and Habermasian accounts of deliberative democracy.

According to John Rawls, and the scholars advocating his approach, public deliberation must meet certain constraints to ensure that citizens are treated as equals. The most important condition is that every claim should be subject to a "public reason test." This implies that citizens should advance only those reasons that are principally acceptable to all. If citizens discover disagreements emanating from their "comprehensive views," that is, from their cultural or religious convictions and beliefs, they ought to pursue a path of what Bruce Ackerman calls "conversational restraint." Obviously, on this account, not every issue deserves deliberative treatment; the scope of public deliberation is restricted to the issues that relate to "constitutional essentials" (political norms and institutions) and questions of basic justice. Accordingly, the suitable spheres for deliberation are also restricted; the advocates of the Rawlsian approach maintain that deliberation should occur only in the state and its institutions, such as courts or legislatures.

In contrast to this rather narrow understanding of deliberation, Habermas and his followers argue that deliberation must be open to all who are affected by its outcome. There should be no constraints on topics as long as what is said can be shown to be pertinent to the issue under discussion. Habermas extends the range of acceptable reasons in public deliberation provided that they meet the "moral justification" requirement of public deliberation. This requires rational arguments that are "in the best interest" of all participants. This constraint aims to promote rational reasons, rather than powerful interests, as the basis of the common good and the path to achieving rational consensus as a result of public deliberation. Habermas is committed to

a conception of rational consensus as a regulative ideal that should guide deliberation and legitimate its outcomes.

Unlike Rawls, Habermas conceives of deliberation as taking place beyond small-scale forums, defining it as a broad communication process, or what he calls "subject-less communication," that occurs in the public sphere. This concept is reflected in Seyla Benhabib's definition of public deliberation as "anonymous and interlocking conversations" and in John Dryzek's notion of "discursive democracy" as contestation of discourses in the public sphere. For Habermas, and those influenced by him, deliberative democracy requires the presence of a vital public sphere, where contestation among citizens, groups, movements, and organizations, and opinion formation can take place. The core function of the public sphere is to identify social and political problems and thematize them in such a way that they are taken up by formal decision-making bodies such as parliaments.

The Systemic Turn

The differences between the Rawlsian and Habermasian accounts are reflected in the recent conceptualizations of public deliberation as micro- and macrocommunicative processes. While microtheories of deliberative democracy tend to focus on deliberation in relatively small groups in structured and formal deliberative forums (e.g., citizens' juries), the macrotheories draw our attention to the discursive side of democracy—the argumentation and contestation that take place within the broader public sphere. More recently, deliberative democracy has taken a systemic turn; it has emphasized that rather than conceptualizing deliberation as something that occurs in either structured forums or the broader public sphere, it is important to recognize the multiplicity of deliberative venues in contemporary democracy. The concept of a deliberative system was originally developed by Jane Mansbridge, who argued that public deliberation should entail multiple kinds and modes of conversation, including "everyday talk."

Applications

Deliberative democracy has been applied to various practical problems and policy areas, including complex divisive issues around the globe such as health care, climate change, policing, or city planning. Deliberative democracy is implemented in practice usually by setting up forums or "mini publics" involving randomly selected citizens. Examples include citizen's juries, which have been created by Ned Crosby in the United States; citizen's assemblies, which were pioneered in British Columbia; and consensus conferences, as developed by the Danish Board of Technology and widely applied elsewhere. One increasingly popular application of deliberative democracy has been the participatory budgeting process as used in Porto Alegre in Brazil, where participants are empowered to make decisions on how to allocate a defined public budget. Deliberative democracy has also been used in the context of public opinion research as a method of developing citizen preferences on difficult issues. The "deliberative polling" suggested by James Fishkin, for example, aims to construct hypothetical representations of what public opinion on a particular issue might look like if citizens had an opportunity to deliberate about it. As Enslin, Pendlebury, and Tjiattas (2001) note, deliberative democracy also plays a crucial role in the context of civic education, and educational theory in general; it helps identify the required knowledge and skills citizens should possess to participate in democratic processes effectively.

The application of deliberative democracy is not confined to local or national politics. Deliberation is claimed to offer the most suitable decision-making mechanism for multilevel polities such as the European Union. Some scholars, such as Dryzek, go even further and argue that deliberative democracy is amenable in global politics, where conventional aggregative decision-making mechanisms, such as elections or voting, are generally implausible.

Critics

Deliberative democracy has been subject to various lines of criticism. Some criticize deliberative democracy for being naively utopian in a world where politics is essentially about unequal power relations and the furtherance of self-interests. These critics point out the gap between the ideal of deliberation and actually existing conditions to justify the impracticality of deliberative democracy in any form. Others acknowledge that deliberation can be practiced but characterize it as an exclusionary and elitist model of democracy that fails to take into account the pervasive differences of race, gender, and class. Agonists such as Chantal Mouffe criticize deliberative democracy for its attempt to build "consensus" among conflicting parties, which they think

only leads to the oppression of differences. Agonists see democratic politics in terms of continued and open-ended struggles and argue for agonism over deliberation. More sympathetic critics, such as Iris Young, raise serious internal difficulties and seek to expand deliberative democracy in ways that can better accommodate the various differences citizens may have. In a similar vein, Nancy Fraser sees the Habermasian notion of the public sphere as a unitary bourgeois construct and expands it through her focus on multiple publics, including "subaltern counterpublics," formed by oppressed minorities. Some of these criticisms have already been incorporated into the theory of deliberative democracy.

Democratic Theory of Education

Democratic theories of education embrace the assumption that society is constituted by citizens with a great diversity of life plans and that individuals' efforts to pursue them can lead to conflict or, at a minimum, questions about the relative distribution of opportunities and resources. Thus, democratic theories of education concern themselves both with authority over the way schools function as institutions with great socializing power and with the capacities and dispositions individuals must develop to sustain democratic social relations from one generation to the next. This entry will discuss a number of such theories, but it will also reject the assumption that all democratic theories of education are to be found in the liberal tradition. Nevertheless, an important theme of the entry is highlighted in the words of one of the liberal tradition's central proponents, Amy Gutmann (1999), who argued that democratic theories of education aim at preparing citizens to engage in "conscious social reproduction" (p. 14).

John Dewey and the Great Community

No account of democratic theories of education can escape the historical influence of John Dewey's legacy, most notably his landmark text, *Democracy and Education* (1916). Here, Dewey embeds schooling in a broader vision of democratic life, which he famously characterizes as "primarily a mode of associated living, of conjoint communicated experience" (p. 87). In that work and others, Dewey explores the relationship of schooling to conscious social reproduction, though his answer might best be described as involving conscious social *reconstruction.* For Dewey, schooling is a powerful socializing experience that helps young people develop the skills, habits, and knowledge that support participation in democratic life. Rather than seeing democratic education as a fixed set of practices or a definitive body of knowledge that might ensure proper socialization, Dewey argues instead that it should be understood as the means by which students learn to engage in forms of inquiry rooted in and responsive to the collective projects of the community. Dewey understood that these forms of inquiry would change and evolve over time and that schooling would need to constantly adjust to both the developmental needs of youth and the forms of knowledge appropriate for a given time and place. Thus, citizens educated in a healthy democracy learn to critique and reconstruct the very institutions and practices that shape their lives now, in order to sustain the foundation of democratic social relations over time. Dewey envisioned schools as embryonic democratic communities, where students learn how

to engage in the process of collective reconstruction and how to find their own paths within it.

Democratic Citizenship, Cultural Pluralism, and Civic Virtues

Democratic theories of education, like their political counterparts, must face the challenge that pluralism presents for any participatory form of governance. Indeed, it would not be unfair to describe this as the most pressing issue for both educational and political theories of democracy. Largely drawn from the tradition of liberal moral and political thought, the approaches considered in this section pursue two related questions: (1) how can decisions about schooling be made when disagreements arise (including differences about the requirement to participate in public schooling at all) and (2) how can students be best prepared not only to live in a pluralistic society but also to prosper from the many benefits that such diversity brings?

Many contemporary answers given to these questions by liberal educational theorists have been informed by the work of the philosophers John Rawls and Michael Walzer. Amy Gutmann (1987/1999), for example, influenced by Walzer, offers a democratic theory of education that seeks to determine the boundaries of authority in making educational—that is to say, political—decisions: "Except by abolishing mandatory schooling, there is no way of avoiding a political decision about the content of schooling, its distribution, and the distribution of educational authority" (p. xi). Thus, rather than trying to settle conflicts over educational policy and practice through the application of some timeless moral calculus, Gutmann seeks a principled way to determine the authority and responsibilities that individuals, families, and the state possess to settle such disagreements. Gutmann's principles of nonrepression and nondiscrimination set limits on the exercise of each group's authority, fostering educational experiences that help students develop the capacities to participate in similar activities in the future. Gutmann's approach eschews barriers to participation (especially by less powerful groups) while remaining responsive to the changing circumstances of life in a democracy and the cultural differences that inevitably constitute it.

Other approaches to answering the two questions posed above focus more directly on the virtues and capacities that schools might seek to develop in students in order to prepare them for life in a pluralistic democracy. As with Gutmann, such theorists begin with the recognition that this requires a form of political education aimed at reproducing democratic social relations in a way that does not diminish or marginalize the diversity of life plans that citizens hold. Eamonn Callan (1997), for example, has this orientation; he draws a distinction between "reasonable and unreasonable pluralism" and posits that education should help students to discern the difference. Common schools are places where students learn to be reasonable, that is to say, they are places where they learn to understand, exchange, and explore the reasons given by others who are different from them.

Many other examples might be considered to give greater breadth to this perspective. Ken Howe (1997), for example, focuses on the concept of equal educational opportunity ("opportunities worth wanting") as a foundation for democratic educational theory. Building on the work of the political philosopher Will Kymlicka (and to some extent on the work of Gutmann as well), Howe argues that by considering the "context of choice" that schools present, we can better see how responsive they are to the multiplicity of identities and life plans that students bring, as well as the barriers to success that many students experience. Meira Levinson (1999) argues that liberal education and liberal politics cannot exist without each other and that their shared commitments require an "autonomy-promoting education" to establish the common deliberative qualities necessary for reasoned exchanges and decisions in the public sphere. David Blacker (2007) argues that schools should be much more permeable to reasonable and competing cultural beliefs, traditions, and groups. For Blacker, deep commitments associated with "comprehensive conceptions of the good" are primary sources of motivation for democratic engagement. In response to the inevitable conflicts that do emerge, Blacker argues that groups must embrace norms of reasonable public discussion buttressed by commitments to a Rawlsian conception of civic friendship.

While the liberal tradition is a rich and robust source of answers to the questions with which this section opened, its ideas have provoked responses from a variety of sources, not the least theorists embracing conservative or neoconservative political perspectives. Rather than seeing cultural pluralism as an inevitable and generative attribute of democratic life, many see these aspects as potential threats to both national identity and social stability. For

example, Arthur Schlesinger Jr. (1998) worries that an uncritical expansion of the academic canon by advocates of multicultural education risks diminishing the core values that hold the nation together. He asks, "When does the obsession with difference begin to threaten the idea of an overarching American nationality?" (p. 81). In a long series of popular books ranging from 1988 to 2009, E. D. Hirsch Jr. has argued that access to the benefits of democratic society depends on the acquisition of a core set of cultural ideas and reference points (i.e., cultural literacy) that democratic schools should overtly teach. He rejects Deweyan progressivism as the source of much wasted effort and ineffective instruction and argues for more direct transmission of this common body of knowledge, especially to students from marginalized backgrounds.

Culture, Power, and Critical Consciousness

Theorists in the critical tradition have long argued for the necessity of a more structural approach to understanding how schools succeed or fail in building and sustaining democratic social relations. These theories focus on the ways in which schooling helps reproduce hierarchies of power and status based on class, race, gender, and other salient aspects of social identity. They often reject liberal theories of education as overly individualistic in their analysis of the roots of contemporary challenges to democracy and as being ill equipped to justify or guide the necessary reforms.

Critical theorists are also interested in how schooling shapes the understanding of students and prepares them to participate in a democratic society. A major difference, however, rests in the starting point of this process. Using concepts from the Marxist tradition, such as ideology and hegemony, critical theorists seek to demonstrate how social institutions like schools can shape the consciousness of individuals in ways that constrain the exercise of democratic deliberation, reduce the capacity for discerning the source and significance of inequality, and reproduce structural hierarchies that sustain class privilege into the future. The relationship of ideology to consciousness is so fundamental, critical theorists argue, that it shapes the very nature and construction of knowledge.

If democratic societies are to be open and responsive to the needs of all citizens, then schools have a crucial role not just in helping students develop capacities related to participation but also in assessing existing forms of knowledge, patterns of social interaction, and norms of institutional practice. These may actually be the product of class interests, and their acquisition a form of oppression or complicity. Schooling should contribute to "illuminating the tendencies for unwarranted and often unconscious domination, alienation, and repression," as Michael Apple argued in his groundbreaking work *Ideology and Curriculum* (1979/2004, p. 126). On this account, students must develop the kind of critical consciousness that allows them to question unexamined assumptions and taken-for-granted understandings of the world in order to discern the interests that may motivate seemingly neutral and uncontroversial knowledge claims, especially those found in school curricula. For teachers, as Ira Shor notes, this entails crucial choices about how to engage students with the curriculum and where they find themselves within it. Critical theorists press for a deeper understanding of the relationship between power, knowledge, and various aspects of education for democracy, including curriculum content, instructional practice, and the organization of schooling.

Future Directions in Democratic Educational Theory: Cosmopolitanism

In contrast to democratic educational theories, most of which assume an individual nation-state or society as the primary unit of analysis, work in cosmopolitan moral theory suggests a different starting point. Cosmopolitanism challenges traditional conceptions of the boundaries of moral obligation and political affiliation—and thus the role of schools in society—by expanding the focus of deliberation to a global scale. Because there is a global common humanity, and because the solutions to global problems require collaboration across state boundaries, cosmopolitan theorists challenge traditional views of democratic education on both moral and political grounds. Martha Nussbaum and Joshua Cohen (1996), for example, argue that one of the primary goals of cosmopolitanism is to reduce the distance between innermost experiences of affinity and the outermost circle of global awareness.

Like other democratic educational theories, such an approach aims at building a variety of capacities related to deliberation and dialogue. Unlike other perspectives, however, cosmopolitan education would confront an even greater diversity of (and conflict among) cultural identities and social

locations. Schooling under these terms would take the familiar virtues and capacities of democratic education (including, for some, the development of critical consciousness) and extend them beyond the customary boundaries of the state. Education for democracy in a cosmopolitan world would focus on building the capacity to engage in authentic inquiry, dialogue, and collaboration across national and cultural boundaries; the capacity for inquiry directed at the fundamental social, political, and cultural structures that shape self-understanding and understanding of others; and the disposition to seek reciprocity with others through perspective taking and mutual exploration of life plans. At its roots, a cosmopolitan education would be guided by a commitment to engage deeply with the processes by which identity, culture, and political systems are constructed and reconstructed over time.

Such an education stretches the notion of "conscious social reproduction" to its limits and perhaps beyond. It is here that Kwame Anthony Appiah's (2006) conclusion is perhaps most appropriate not only for cosmopolitanism but for all democratic educational theories: "Cosmopolitanism is the name not of the solution but of the challenge" (p. xv).

Deschooling Society: Ivan Illich

In education, Ivan Illich (1926–2002) is closely tied to his most famous book *Deschooling Society*. This book not only featured a radical critique of modern education institutions that were undergoing unprecedented expansion in the 1970s but also offered a set of proposals or guidelines for anyone intent on creating a world without schools. Furthermore, in this book, Illich experimented with a new critical study of educational institutions. He considered that beyond the rituals of schooling and the culture of social reproduction that fed the schools, a justificatory and legitimizing discourse could be discerned. Illich placed this discourse into the context of the U.S.-driven developmentalist policies of the second half of the 20th century. In an environment of deep systemic restructuring happening worldwide, the idea of progress was the background to school expansion. As a result, as was stated in *Deschooling Society*, fighting against development and progress imposed by capital meant fighting with the very institutions that supported them. One such institution was the school.

Deschooling Society was the book that had the most impact of all the books that Illich produced in the 1960s and 1970s, the time when he took up residence in the city of Cuernavaca (Mexico). He railed against schools as the institution that was the depository of the highest aspirations of Western societies, which led to an unprecedented uproar in academic circles as well as in many of the social movements that still believed that educational institutions were capable of solving society's biggest problems. In addition, those who in the mid- to late 20th century had set out to organize alternative spaces for learning that were different from the official education

systems found that *Deschooling Society* gave them new material for criticizing schools while opening up a range of pedagogic alternatives that could be exploited and implemented. Furthermore, many of these alternatives also involved a change in perspective regarding the use of the existing technology, which in turn involved a change in the conception of the relationship that a society can establish with the technology it is capable of creating. In place of the corrupting influence of educational institutions that treated education as a commodity, Illich proposed the establishment of "learning webs" (which could be facilitated by the emerging computer technologies), wherein skills and knowledge could be passed on through peer-to-peer voluntary contact. In a sense, it may be said that Illich amply carried out the latent objective in his work: to break the myths around schools and schooling.

Illich did not content himself with laying out the theoretical lines that justified the thinking of a society in which education was de-institutionalized. Rather, he also put into practice many of his postulates at the center that he and a tight-knit group of collaborators opened in the Mexican city of Cuernavaca: the Centro Intercultural de Documentación (CIDOC; International Documentation Center). Open from 1963 to 1976, this center became a space of international renown where avant-garde intellectuals and politicians came from all over the world to study, research, and converse. Along the hallways of Illich's center could be found the likes of Paulo Freire, Peter Berger, Erich Fromm, Paul Goodman, Enrique Dussel, André Gorz, Jean-Pierre Dupuy, Augusto Salazar Bondy, Susan Sontag, John Holt, Everett Reimer, Francisco Julião, Octavio Paz, and others. Sweeping sectors of the social protest movements also took part in activities there, and the center helped bridge the gap with the emerging counterhegemonic and counterculture sectors that were turning Latin America into one of the most outstanding political laboratories on the international scene.

Currently, a careful reading of *Deschooling Society* may be more worthwhile for the historian studying the mind-set of the 1960s and 1970s than for someone who now wishes to study minimally feasible alternatives to traditional schooling. When analyzed in the shadow of the philosophic, economic, sociological, anthropological, or historical approaches of the past 40 years, Illich's book comes across as an imprecise essay that adopts an outdated methodology. It is worth mentioning that Illich himself detected many of these theoretic blunders in *Deschooling Society* in later decades. In fact, in an introduction to the book by Matt Hern titled *Deschooling Our Lives* (1995), he even wrote that his critique in the 1970s of educational institutions was a naive effort at understanding the discursive complexity that upholds and reinforces education and its institutions in the modern world (e.g., the influence of the family, mass media and advertising, and economic institutions was downplayed). More than 20 years after it was first published, he considered that the texts making up *Deschooling Society* in some ways were a sincere effort at bringing to light the damage done to the world by the spread of the institutionalization of learning, although they were mistaken because he himself at that time had been barking up the wrong tree in his attempt to configure a criticism of the modern institutions of education.

Design Experiments

Introduced in 1992 in the educational research literature in two seminal articles by Ann Brown and Allan Collins, a design experiment (DE) is a method

of inquiry that embodies what is today commonly called design-based research. A major characteristic is that a DE involves the development and application of an instructional intervention in a genuine educational setting. Complaints about the disconnect in education between research and theory, on the one hand, and educational practices, on the other, are still the order of the day. In view of bridging this gap, DEs have a twofold goal: advancing theory building about learning from instruction while at the same time contributing to the fundamental innovation and improvement of classroom practices. After a more detailed description of the characteristics of a DE, critical discussions of DEs will be addressed, and a final comment will be made about the current status of design-based research.

Basic Characteristics of DEs

According to Brown and Collins, DEs aim at the development of a design science of education that can guide the design and implementation of novel effective learning environments. In terms of Donald Stokes's quadrant model of scientific inquiry, DEs can thus correctly be situated in Pasteur's quadrant (named for the research of Louis Pasteur), which represents use-inspired basic research. Indeed, DEs aim at the simultaneous pursuit of the advancement of our understanding of the processes of learning and instruction, on the one hand, and the innovation and improvement of classroom practices, on the other. In that perspective, a key feature of a DE consists of the *theory-driven* creation of an educational intervention: Designing the intervention draws on the available evidence-based knowledge about productive learning and effective teaching that derives from multiple disciplines, including developmental psychology, cognitive science, the learning sciences, educational technology, curriculum theory, instructional design, anthropology, and sociology. But a DE is also *theory oriented*: It is anticipated that the implementation and evaluation of the intervention will contribute to the continuous development and elaboration of theory.

To warrant as much as possible that DEs will result in principles and artifacts that can lead to the innovation and improvement of classroom practices, the design of interventions takes place in an interactive collaboration among researchers and practitioners, and the interventions are implemented and evaluated in regular classroom contexts. Both aspects are essential conditions in view of achieving effects in the real world. A special feature of most DEs is also that they run over a long period of time and involve multiple iterations, that is, the intervention is flexibly adjusted, refined, and improved as it unfolds during the course of the investigation.

To assess the effects of an intervention in a DE, multiple mixed methods—quantitative as well as qualitative—are used in an integrative way to assemble and cumulatively construct a body of evidence that supports the underlying theoretical principles of an innovative approach to learning and teaching. It is important not to confuse design-based research and action research. There are similarities among these two research strategies: Both address real educational problems and set up actions in collaboration with practitioners who aim at solving them. However, whereas action research focuses on meeting local needs, the major goal of design-based research is the development and elaboration of theory that can guide the design of powerful learning environments.

Critical Discussion of DEs

Since its emergence two decades ago, DEs have received growing interest in the educational research community, as is evidenced by the fact that in 2003 and 2004 three major journals in the field published a special issue devoted to design-based research: *Educational Researcher*, 2003, Vol. 32 (1); *Journal of the Learning Sciences*, 2004, Vol. 13 (1); and *Educational Psychologist*. However, besides enthusiasm about the potential of DEs to contribute to bridging the disconnect between research and practice, this methodological approach has also evoked criticisms that mainly relate to objectivity, concern about data selection, lack of rigor, and the possibility of simultaneously contributing to theory building and improvement of educational practices.

The problem of objectivity arises because in a DE the researcher is also a participant in the development and implementation of the intervention and thus adopts two potentially conflicting roles. Ann Brown herself raised the danger of biased interpretation of data in the direction of the researcher's expectations in her 1992 article, referring to it as the *Bartlett effect*. The second criticism concerning data selection—also already discerned by Brown—aggravates this problem and derives from the iterative nature of design-based research. Indeed, the iterations result in an excessive amount of data from which the researcher has to make a selection

for analysis. It is of utmost importance that design-based researchers are aware of these problems that can jeopardize objectivity. An approach suggested by the Design-Based Research Collective to warrant as much as possible this objectivity consists in using triangulation of a variety of data from multiple sources.

From the perspective of the canons of experimental research, DEs are criticized, for instance, by Joel Levin and Angela O'Donnell, for lack of rigor, especially for the confounding of variables and the lack of randomization. Both issues derive from the fact that in a DE complex interventions are engineered and implemented in a rather small number of naturalistic classroom settings. Because of the complexity of the learning environments in DEs, it becomes impossible to disentangle the relative contribution of the different variables involved in producing the effects of the intervention. Furthermore, moving into the everyday reality of self-contained and often messy classrooms easily conflicts with the canon of randomization, the more because in many cases no control classes are involved. However, one can argue that the systemic approach of DEs is nevertheless appropriate and defensible when the focus of interest is to evaluate the quality and effectiveness of a multicomponential intervention. Of course, this approach should be complemented with more rigorous randomized classroom trials. Indeed, as argued by Susan McKenney and Thomas C. Reeves, increasing the methodological robustness is a challenge.

Single DEs can certainly not lead simultaneously to theory building and the improvement of practice. However, analysis of the now available literature on design-based research, for instance, in a recent article by Terry Anderson and Julie Shattuck, seems to support this potential of DEs. It is plausible that through sequences of intervention studies, combined with more controlled investigations, DEs can contribute to the advancement of theories of learning from instruction by exploring the potential of novel learning environments and developing contextualized theories of learning and teaching.

Final Comment

As argued by Terry Anderson and Julie Shattuck, the application of DEs has increased over the past decade, and this is certainly also due to the positive effects on student outcomes. One can say that today design-based research has acquired the right to exist in educational research. However, so far the success of this methodology is restricted to small-scale interventions. Expanding the approach on a larger scale is a major challenge for the coming years.

Dewey, John

John Dewey (1859–1952) was a founder of American pragmatism and a major figure in the progressive education movement, which flourished in the early to mid-20th century. Born in Burlington, Vermont, where he attended public school, Dewey went to the University of Vermont, where he became interested in philosophy. After graduation, he taught briefly in Oil City, Pennsylvania, known (as its name suggests) for its early role in the petroleum industry.

Dewey was born the same year as Darwin's *Origin of Species* (1859) was published, and one year before the Civil War began. Both events would prove to be landmarks for Dewey's thought: Darwin because his ideas about evolution permeated Dewey's

philosophy; the Civil War because Dewey inherited and advanced the new understanding of industrial democracy that it inaugurated. Indeed Dewey was as much an *American* philosopher as Walt Whitman was an American poet or Mark Twain an American humorist. As a man, he reflected his times and place; as a philosopher, he worked to understand how to direct the energy they produced toward democracy; as an educator, he worked diligently to reform schools and to reconstruct our understanding of the educational process.

Dewey was a philosopher of the industrial and scientific age. Only 10 years before his birth, the railway first connected the East Coast to the Great Lakes, and 10 years later, it was extended, reaching from the East Coast to the West. Before he died, a message could be transmitted overseas by phone in seconds, roads tied together every part of the country, and transcontinental jet air travel was poised to become commonplace. Dewey was also a philosopher of transformation, living through two world wars: He saw the country altered from a minor player on the international stage to the most powerful country on earth. And he was a philosopher of liberal democracy, working to ensure that democratic traditions survived and flourished in an age of great wealth and technological expertise. Dewey's philosophy reflected these changes and articulated their significance as he strove to understand their implications for philosophy, for education, and for everyday life.

As important as the Civil War (1860–1865) was in the rebirth of the nation, Dewey came to understand that it had not fulfilled Lincoln's promise of a rebirth of freedom. Women still could not vote; industrial workers were exploited; immigrants were discriminated against and oppressed, while Blacks were systematically terrorized.

Like Karl Marx, Dewey felt that the new industrial age provided liberating possibilities, and like Marx too, Dewey understood that there were many roadblocks that needed to be addressed before these possibilities could be realized. He rejected traditional philosophy because of its antiscience bias and pointless quest for certainty; he criticized the schools of his day for their outdated methods; he objected to the irrational authoritarianism of religion, and he condemned the selfish exploitation of labor by profit-hungry capitalists. Yet Dewey believed that these were but roadblocks to the fulfillment of democracy, roadblocks that could be removed by educational reform and the exercise of social intelligence. This belief would be sorely tested during his lifetime.

Dewey's Early Life and the Development of His Thought

In 1884, Dewey received his doctorate from Johns Hopkins University, the first research university in the United States, which was based on the German model. He had studied under the neo-Hegelian G. Sylvester Morris (1840–1889) and was heavily influenced by Hegelian idealism. But whereas Hegel (1770–1831) saw human history as a predetermined unfolding of an already present destiny, Dewey would soon come to embrace the more open-ended, probabilistic understanding of life advanced in different ways by the naturalist Charles Darwin (1809–1882) and by American pragmatists such as William James (1842–1910) and Charles S. Peirce (1839–1914).

After publishing his first article in the *Journal of Speculative Philosophy*, edited by the prominent Hegelian educator W. T. Harris (1835–1909), and completing a dissertation on Kant, Dewey took his first teaching position as an associate professor at the University of Michigan in 1884. In 1894, he became head of the Department of Philosophy, Psychology, and Pedagogy at the newly founded University of Chicago, where he also served as director of the University Laboratory School.

In Chicago, influenced by the social reformer Jane Addams (1860–1935) as well as by his wife Alice (1859–1927), who served as principal of the Laboratory School, Dewey began to address the condition of immigrants and industrial workers. In 1904, Dewey resigned from the University of Chicago after a bitter and irreconcilable dispute with its first president, William Rainey Harper, over Dewey's control of the expanded Laboratory School and the unexpected firing of his wife. He was quickly hired by Columbia University, where he had a position both in the philosophy department and at Teachers College. He retired from Columbia in 1930 but continued to hold an office there until his death in 1952. During his life, Dewey's influence spread throughout the world; his works were translated into many languages, including Chinese, Japanese, and Turkish.

Dewey and Pragmatism

In addition to Darwin, the main influences on Dewey's mature thought were the American pragmatists Charles Peirce and William James, along with Dewey's colleague the sociologist George Herbert Mead (1863–1931). Pragmatism, which flourished from the late 1800s to the 1950s, was a response

to the rapid changes in American society in the post–Civil War period. It emphasized science and experimentation while de-emphasizing traditional metaphysics and, in Dewey's terms, "the quest for certainty." Pragmatism broke from traditional philosophy by denying that truth could be construed as a claim that lined up some inner mental event, such as ideas, with some pure and simple external reality. Rather, the test of truth, or what Dewey would refer to as warranted assertibility, was attained through the systematic, ongoing, self-corrective process of science.

The key to pragmatism was first laid down by Peirce when he affirmed that beliefs are simply rules for action. To say, for example, that *X* is harder than *Y* simply means that *X* can scratch *Y* and that *Y* cannot scratch *X*. James (1991) extended Peirce's ideas about meaning into a general pragmatic method: The pragmatic method means "the attitude of looking away from first things, principles, 'categories' supposed necessities; and looking towards last things, fruits, consequences, facts" (p. 27). For Dewey, thought is initiated by the problems we confront and is tested by our success or failure in confronting them. A problem arises out of a disruption in our habituated response that interrupts the flow of activity, producing a felt tension. Thinking is then the systematic process of deliberation that seeks to overcome this disruption and relieve this tension through inquiry. Reason is a tool that enables us to solve problems, to renew experience, to get on with life, and to reweave the flow of activity.

Thinking then entails both a conservative and a liberating element. It is liberating insofar as it projects alternatives and allows us to act on the most promising way to remove obstacles and to renew the flow of experience. It is conservative insofar as it connects these alternatives and evaluates them not only by how well they remove the roadblock but also by how well they cohere with the network of other habits that constitutes a self, and by how consistent the new beliefs are with prior beliefs and habits that are not up for consideration at the present. Thinking bridges the old and new. Should the new belief be too radical, it is in danger of being impractical utopianism. Should it be too conservative, it would encourage repeating dysfunctional and self-defeating behaviors.

Dewey as Philosopher

Dewey was both a philosopher and a public intellectual. He acted on his belief that philosophy should not just address the problems of philosophers, as he believed had been the preoccupation of philosophers in the past. At a time when science was largely associated with the physical and biological realms, he argued that the methods and spirit of science be extended to the social world as well. He argued that philosophy's concern must be the "problems of men" informed by science, for the sake of individual growth and enriched democracy. Traditional philosophy's quest for certainty and absolute truth should be abandoned, and replaced by whatever science will allow us to claim and however long it will allow us to claim it.

Dewey's educational and social philosophies were directly linked to his unique understanding of both science and democracy and of the possibilities that they have to enhance the life of individuals. For Dewey, the importance of science was more than its findings. Science suggested both a way of thinking and a way of being, and each he felt was essential for democracy. As a way of thinking, science was seen as a process of systematically reflecting on and refining belief in to improve individual experience and social life. As a way of being, science involved a community engaged in reflective thought, where evidence is public and available for all to see and where a careful consideration of evidence will be used to decide differences and formulate consensus. Essential to them both was a certain kind of temperament, an emotional spirit that is not only open and inquiring but also critical.

Dewey rejected the passive psychology inherited from empiricists like John Locke (1632–1704) and the view that knowledge consisted of imprinting sensations on the mind, conceived of as a blank slate. The problem with this view, according to Dewey, was both philosophical—it had an inaccurate understanding of human conduct—and practical—it spawned destructive social forms and led to inhuman working conditions, economic uncertainty, and destructive educational practices. Dewey rejected the view that human beings were blank slates waiting for experience to write its lessons on them. Humans were not simply passive and inactive beings driven toward pleasure and away from pain. They instead were active agents engaged in soliciting the cooperation of their environment, including their human environment, to solve problems and enhance self-control. Knowing involved an engagement with the world as humans seek to control experience for the sake of richer experience. Rational deliberation, as a rehearsal of different possible courses of action,

engages concepts to promote control. Good concepts are not to be understood as accurate representations of a world "out there" but are tools that enable us to engage the world in more and more predictable and effective ways. Concepts are a lot like shovels and hammers, tools that enable us to get on with activity when obstructions bar our way. And just as we seek new tools when hammers and shovels are not sufficient, so too do we engage new concepts when old ones are inadequate to the task. Moreover, ideas not only help us reorder our own activities, they are ways of redirecting ourselves, of rethinking our own goals and responses to them, and thus of reshaping our own character. And what is true of the individual is also true of the community. In contrast to social Darwinists, who believed that Darwin's notion of natural selection required a competition "red in tooth and claw," in which concern for one's fellows was a weakness that would result in individual or even species extinction, Dewey argued that cooperation enabled humans to control nature and survive and was indeed the foundation of the success of our species. Dewey's liberalism was thus founded not on the selfish individualism of Thomas Hobbes (1588–1679) or on the indifferent individualism of Locke but on a new social individualism where the aim of society is to enhance the unique qualities and potential of each individual and the aim of each individual is to advance the potential for social cooperation.

Yet if Dewey differed from the strict social Darwinists, who saw having traditional moral ideals as weakness, so too did he differ from those who believed that moral and ethical principles were absolutes that could bend to neither time nor events. Hence, Dewey ran afoul of religious as well as biological absolutists—of those who thought moral ideals were absolute and unchanging as well as those who held that they were self-defeating. For the latter, his relativism was as bad as the former's nihilism, while for the former, it was as delusional as the latter's absolutism. Yet Dewey was simply recognizing that different times yielded different opportunities and that different opportunities required different rules of conduct.

For Dewey, the danger for his time was rampant individualism, which he saw as an outgrowth of the old liberalism, a philosophy that Dewey felt had once serviced human need and aided the development of human potential but had now run its course. Now the old liberalism had become a rationalization for economic uncertainty and abusive labor practices, a justification for laissez-faire competition between individuals (if not corporations), an ideology of the economically powerful. In short, Dewey felt that it had become a theory at the service of the rich, justifying destructive competition and blocking opportunities for constructive coordination and the release of human potential that advances in science and technology made possible. Of course, Dewey was not the only theorist to object to the trajectory of liberalism. Karl Marx had a similar insight. However, whereas in Marx's thought progress would come only through revolution, Dewey placed his hope in democracy, education, and the method of science.

Dewey's Philosophy of Education

Dewey's educational theory was formed in the late 19th century during a period of great turmoil about the future of traditional education. An increasing number of states in the United States were making education compulsory until the age of 16 (this level of education had been rare just a few years before); immigration was increasing at a rapid rate, and immigrants were arriving from more diverse areas; working-class children were attending school in ever greater numbers as America was undergoing the transformation from a rural farming society to an urban industrial one. These changes were accompanied by the growing attack on the traditional curriculum, an attack launched by educators such as Francis Parker, by popular journalists such as the muckraker Joseph Mayer Rice, and by respected experimentalists such as E. L. Thorndike, a colleague of Dewey's at Columbia.

As an educational theorist, Dewey straddled two competing standpoints. On one side was W. T. Harris (1835–1909), who advocated academic rigor and subject matter proficiency. For Harris, these were the keys to national prominence and power. On the other side were educators such as Francis Parker (1837–1902), often called the father of progressive education, who romanticized childhood while advocating schools that drew on the natural interest of the child for their motivational energy rather than a strict discipline regime. Dewey steered a middle and experimental course. Like Parker, he saw the child as naturally active and interested, but he believed that this activity needed to be focused and made more thoughtful and that the child's interests needed to be cultivated. Hence, he agreed to some extent with Harris about the necessity of school subjects like history, geography, and science.

Yet whereas Harris emphasized the connection between subject matter and national power, Dewey emphasized their importance to the growth of the child and social progress. These aims determined his understanding of both content and method. For Dewey, subject matter needed to be taught for the sake of enhancing the student's experience, including experience gained by an appreciation of the aesthetics of the disciplines and the value of inquiry. Hence, the right kind of discipline was the one that attached the child's natural interests to the subject matter. It was socially supported self-discipline in the service of growth, or the increased control over the quality of experience. Dewey was making a philosophical point—that method and subject matter can be separated only for the purpose of analysis—but he was also making a political one.

At the time when Dewey began writing about education, there was a growing mismatch between the character of the students in public schools and the largely irrelevant and often mind-deadening methods of an expanding educational system. For Dewey, the problem was not just to attend to the interests of the child, as it was for Parker. It was also to promote shared interests, a sense of the value of participatory democracy and social cooperation. He was concerned about democratic social cohesion and how it might be achieved given the tremendous demographic and social changes of the time. Drawing on his experience in rural Vermont, Dewey believed that in the past, social cohesion had been accomplished through the transmission of communal aims through the face-to-face interaction of different generations in rural communities and their networks of local markets and churches.

Dewey believed that the link between means and ends was much easier for the child to understand when work and life were linked together—as he felt they had been earlier on the farm in a place like rural Vermont. Children learned to understand the long-term consequences of their action through planting a crop, caring for it, harvesting it, and using it. Moreover, they learned the "moral" value of their work because they saw its effect on the family. Life had a natural and transparent rhythm where the consequences of action were clear. In Dewey's perhaps idealized view, work had been tied to home life, and children learned how to execute their future roles by working alongside their mothers and fathers and by being slowly inducted into a caring community of family, friends, and neighbors. Industrial society changed much of this, and because many children no longer worked alongside their parents and because more specialized division of labor took work out of the home, making its method and meaning less transparent, Dewey feared that the connection between learning and doing was being lost for children. His educational theory was intended to maintain this connection in the context of formal schooling. In the lab school, activities like sewing, weaving, and the like introduced children to their social heritage and initiated more thoughtful inquiries. Children were taught no longer to take the fruits of everyday life for granted but rather to understand their source in a deep, experiential way. For example, they might pluck cotton out of cotton bolls, card it, spin it, weave it, dye it, and then reflect on the importance of the cotton gin and on why historically wool was used earlier than cotton. This activity then might be connected to lessons in history, geography, science, and the like.

Critics complained that children were undisciplined and that there was too much play in Dewey's educational proposals. However, for Dewey the distinction between play and work was an overly rigid division impoverishing the ideas of both play and work. He contended that the two terms should refer to the immediacy or the distance of the fruition of an activity; in play, the fruition was close, and in work, it was more distant. Through play, he felt that he could both introduce subject matter in a meaningful way and promote the social role of the school. As children became older, the distance between act and fruition could hopefully become greater. Yet the opposite of play for Dewey was not work but meaningless labor, just as the opposite of work is meaningless frivolity.

Dewey suggested, perhaps somewhat naively, that earlier communities—like the Burlington of his childhood—had been models of participatory democracy, and he was hoping to find a substitute in the public schools that he hoped might spur increased participation and democratization in the workplace. Dewey looked forward to a time when teachers, committed to and trained in democratic pedagogy, would become the new moral guides educating future citizens in the ways of participatory democracy. He also believed that many of the conflicts that immigrants brought with them from Europe—some religious, some rooted in national differences—could be assuaged by a democratic public education system that promoted scientific values and social consensus and through these the continual formation and reformation of both individuals

and their communities. His test for democracy was both social and individual. A democratic education promoted the growth and variety of shared interests among different individuals as well as the freedom to associate with other groups in the fullest possible ways.

The concern to tie understanding to interest and action did not mean for Dewey, as some of his critics have alleged, that schools should ignore traditional subjects for the sake of the child's momentary interest. If there was a problem, it was not with the subjects themselves but with the way they were packaged by curriculum developers, who presented to students a refined, abstract finished product based on adult understandings, without concern for the way this presentation comported with the students' need for meaning and significance. Educators needed to understand that the child's interest did not always correspond to the way traditionalists had carved up the world—into discrete subjects—and that the psychology of learning must inform the logic of the subject matter.

This educational program was backed up by more than just common sense. It was also supported by powerful psychological insight about the interrelation between a self and its environment, an insight expressed in Dewey's groundbreaking article "The Reflex Arc," in which he criticized the rigid distinction between sensation, thought, and act by arguing that sensory stimulus, central connections, and motor responses are not separate and complete entities in themselves but are best understood as functions within the single concrete whole, where each serves to influence the other and where the unity of the whole "determines the values of its constitutive factors." In other words, a coordinated act flows; its longer- and shorter-run aspects inform one another—it is not just a series of disjointed parts. Its parts reinforce one another in an organic way, and means and ends are connected in an efficient and satisfying way. The article served, by implication, to challenge the view that students were passive learners who, like animals, when provided with the right reinforcement (positive or negative), would learn whatever was required of them. Rather, when educated in this way, they would grow into adults who tolerate meaningless work and illegitimate power.

Dewey's Educational Writing

Dewey wrote many books and articles on education. Among the most important books are *School and Society* (1899/1990), *The Child and the Curriculum* (1902), *My Pedagogical Creed* (1897), *Democracy and Education* (1916), *Schools of Tomorrow* (1915, with Evelyn Dewey), and *Experience and Education* (1938). In addition, he wrote numerous articles on topics such as coeducation, intelligence tests, and vocational education. While the emphasis changed depending on the circumstance and the audience, the core message was remarkably consistent. Democracy requires a democratic education, and a democratic education must be predicated on encouraging a spirit of community and mutual inquiry.

For Dewey, education is the process by which immature individuals come to participate in the social consciousness of the human race. The process begins at birth and lasts a lifetime. Hence, for Dewey, education is both wider and deeper than formal schooling and includes more than simply the transmission of the vocational and life skills that one requires to get along. It also involves children coming to consciousness of the inherited skills of the group as they take on its aims as their own and identify with its history and its fate. Because education is nothing less than the process by which a community renews itself, it is also the concern of the entire community. This is the reason for Dewey's much-quoted statement found early in *School and Society*: "What the best and wisest parent wants for his own child, that must the community want for all of its children" (1899/1990, p. 7).

Dewey distinguished between informal education, which is the renewal of social life from one generation to another by social participation, and formal schooling, which is a specialized formal institution designed to regulate transmission for some purpose. Formal schools come into being when society grows in complexity and when many of its traditions are stored in written texts. The school, Dewey tells us, is an agency that is consciously designed to do what is done more informally in simpler forms of social life in the family and community.

Like most progressives, Dewey was a harsh critic of many of the practices of the schools of his time. Existing schools worked to prepare students for some future life while removing subjects like math, science, geography, and history from life experience. Skills were taught as, say, one might teach students how to hold and swing a hammer without ever telling them about nails. Subjects were presented as fixed points for the child to reach, disconnected from the child's own experience. In contrast, Dewey believed that with proper guidance school subjects

could be connected to the child's ongoing everyday experience, serving to inform and deepen it while transforming the child's interests and connecting it to that of the wider community. He believed that the time was ripe for a new progressive approach, such as was practiced in his own laboratory school at Chicago. In *Schools of Tomorrow* (1915), he and his daughter Evelyn provided a survey of a number of existing experimental schools that manifested some aspect of the progressive idea.

In *Democracy and Education* (1916), Dewey's most comprehensive work on education, he argued that education and democracy are inseparable. They are intermingled forms of associative living in which growth, individual and communal, is primary. Dewey proposed that education is the process of social renewal, where social skills are reproduced in each new generation and where each new generation comes to share in the interests of the group. Not all societies require formal education. Where the division of labor is simple and where work is carried on in the home, children learn the skills they need informally without systematic instruction, and through face-to-face encounters with adults, they come to identify the community's interest as their own.

Formal schooling becomes necessary as the division of labor intensifies, as work is separated from the home, and as skills become more and more complex. Yet as work becomes more complex, as children spend less time at home, and as the division of labor increases, the danger of communal disengagement becomes greater, and the connection between learning and doing threatens to become more distant. *Democracy and Education* serves as a roadmap for reconnecting learning and interest. It is also a roadmap for reconstructing the idea of democracy from a way of governing to a way of living. For Dewey, the goodness of a society is measured by how numerous are the connections between its members, and how open its members are to the formation of new interests and new associations.

Although Dewey often made the point that education was not preparation for some distant future, he did not mean that education should be indifferent to the capacity of the child to function later in life. He meant that preparation for life must not defer meaning to some future time. It must begin by taking into account the experiences that children bring to the school from their life outside. For Dewey, if the active nature of the child is to be preserved and her experience deepened, then the subject matter must connect in some organic way to the ongoing life experience of the child. The danger of strictly formal instruction is that the connection between the child's experience and the significance of the subject will be obscured, and in the process curiosity will die. The teacher's task is to provide an organic connection between the child's past and present experience and the subject that the child is expected to understand. The subject matter is to be used to link the child's present concerns to future enhanced powers, control, and enriched experience.

The School as a Form of Social Life and Renewal

There is some question whether Dewey changed his understanding of education over time. His early optimism that schools could be at the forefront of progressive change was developed at a time of increasing immigration and as the country was changing from a rural, farming society to an urban, industrial one. Moreover, *My Pedagogical Creed* (1897) was published before compulsory education to the age of 16 became universal, and while the country was still in transition. While he may never have lost hope that the school would become the principal agent of progressive social change, his last major work on education, *Experience and Education* (1938), was more critical of progressive educational practices as they had developed, and this book is often seen as attempting to correct the balance between emphasis on the interests of the child and concern with the importance of the subject matter. In point of fact, Dewey always acknowledged the importance of both, but at different times he would highlight one over the other. Hence, for example, both *The Child and the Curriculum* (1902) and *School and Society* (1899/1990) were written while Dewey was involved with the Laboratory School at the University of Chicago, and they describe and justify the work that went on in that school, with its child-centered approach to learning. After he left Chicago and the Lab School, Dewey continued to write about education and to develop his ideas about its relation to democracy, but with greater concern for its implication for the future of a democratic nation. Certainly there were many changes in emphasis as Dewey responded to the changing times, but the basic themes about the need to connect ends and means, subject matter and method, individual and society, work and play remain throughout.

The Influence of Dewey Today

After his death, Dewey's influence on American philosophy declined as philosophers looked to England and continental Europe for new inspiration. Progressive education suffered a similar fate as its ideas came under criticism as being responsible for America's purportedly weakened position in the Cold War. Many critics believed that progressive education was somehow inconsistent with high-level education in math, science, engineering, and foreign languages, areas thought most essential for Cold War conflict. In more recent years, Dewey and progressive educators have been criticized for setting in motion an educational system that weakens the country's economic prowess. Many of these claims rest on a caricature, but they have fueled much recent educational reform. This reform promotes greater standardization of schools, with more rigid discipline, standardized tests, and teacher accountability. Nevertheless, Dewey's influence, while more diffuse, still has considerable standing among educational theorists and can be found in movements as diverse as the open education movement of the 1970s and the feminist and critical pedagogy movements of today. Today, Dewey's ideas form the backbone, often unacknowledged, of the "loyal opposition" to government-directed education policy and serve as a reminder that education must serve more than the economy.

In philosophy, Dewey has also experienced a remarkable revival, in part due to the conversion of the analytic philosopher Richard Rorty to Dewey's brand of pragmatism, as well as the development by the logician Hilary Putnam of the pragmatic grounding of much of his own work. In addition, the continuing work of the Dewey Center at Southern Illinois University in Carbondale continues to maintain the Dewey legacy by maintaining his papers and supporting high-quality Dewey scholarship. Similar centers devoted to Dewey's work can also be found in other parts of the world, and every year conferences are held on pragmatism and on Dewey in a number of different countries. The title of *The European Journal of Pragmatism and American Philosophy* is an indication that Dewey's ideas are still alive throughout the world.

DIALOGUE

Dialogue has been seen as a form of interpersonal communication that emphasizes the open exchange of ideas and mutual respect, and it has a long history in the context of education. Plato (ca. 437 BCE to ca. 347 BCE) is credited with systematizing the genre as a form of pedagogy in his philosophical writings. This entry explores the close connection between dialogue and education, beginning with normative views that hold up dialogue as a pedagogical ideal and continuing with a review of recent critiques of dialogue that point out some of its purported limitations as an approach to teaching, particularly in multicultural settings. The entry concludes with a discussion of the practice of dialogue, exploring issues such as silence, activist versus deliberative communication, and the challenge of fostering open, responsive communicative relations within educational settings.

The Normative Tradition

Largely through the legacy of Plato's philosophical dialogues, and the deference accorded to something called "the Socratic method," dialogue has come to hold a central place in Western views on education.

The idea behind the Socratic approach to dialogue, perhaps best exemplified in the *Meno*, is that a guided process of inquiry will secure a grasp of knowledge that is not dependent on the status of authority or tradition: that dialogue teaches how to think in a way that produces an autonomous, skeptical learner. To what extent we see Socrates consistently teach this way in the dialogues, whether this approach to teaching is properly considered a "method," and whether it is a single unified method have all come into question. Nevertheless, a broad commitment to teaching through dialogical questioning has been derived from this canonical source.

More recently, the Brazilian educator Paulo Freire (1921–1997) added a new dimension to this tradition: the idea that dialogical teaching is also more democratic, more egalitarian, more humane, and more liberating (compared with more didactic and, for Freire, oppressive, "monological" modes of instruction). His ideas add to the epistemological weight Socrates gave to pedagogical dialogue an additional quality of political and ethical obligation, namely, that a teacher committed to progressive values *must* rely on dialogical methods.

The Critical Tradition

This normative stance toward dialogue has come under criticism from the feminist, poststructural, and postcolonial perspectives. Perhaps the most influential of these criticisms has come from Elizabeth Ellsworth (1989, 1997). The central issue raised by her work can be described as interrogating the *unconscious* of dialogue. The aim is to look beneath the surface of overt meanings and expressed intentions, to examine what is *not* being acknowledged or talked about. The danger of dialogue, which represents itself as an open conversation in which anyone can speak and any topic can be broached, is that certain people may not be speaking, certain things may not be spoken—or may not even be speakable in the terms tacitly valorized by the dialogue. Precisely because the surface level of the engagement *is* so apparently reasonable, inclusive, and well intentioned, what gets left out, or who gets left out, remains not only hidden but is subtly denigrated. If you cannot (or will not) express yourself in this manner, the fault lies with you. In pointing out what is *not* open about dialogue, Ellsworth and other critics want to reveal the reverse side of ostensibly "inclusive" educational practices, such as dialogue, to expose what is, in practice, *exclusive* about them.

Alison Jones (1999, 2004) highlights a related problem of dialogue in contexts of cultural difference. The *desire for dialogue*, as she puts it, can carry its own kinds of coercive influence. When people from different backgrounds try to discuss their experiences and differences—as often happens in multicultural classrooms—they are put in asymmetrical positions of risk and self-disclosure. Who are these conversations for, and whom do they benefit? When multicultural educators talk about the virtues of cross-cultural understanding, this is tilted almost always in the direction of the supposed benefits of dominant groups coming to better understand members of nondominant groups. Jones challenges this aspiration. For one thing, members of nondominant groups often have to expend much more time and effort explaining themselves to those who belong to dominant groups than vice versa; indeed, members of nondominant groups may already understand a great deal about the dominant culture. There can even be a kind of voyeurism: "Dialogue and recognition of difference turn out to be access for dominant groups to the thoughts, cultures, lives of others." For Jones (2004),

> the desire for the embodied other . . . may also be a desire for redemption, or forgiveness, on behalf of the white students. . . . The dominant group seeks its *own* inclusion by being rescued from its inability to hear the voices of the marginalized. (pp. 64–65)

In such cases, Jones says, members of nondominant groups may hold back from participating in the conversation, remaining silent as a strategy of self-protection or even seeking to withdraw from the common classroom space entirely.

The Practice of Dialogue

Standing back from these particular criticisms, what has occurred in the educational literature is a move away from an idealized, normative conception of dialogue to a cultural politics of dialogue; dialogue is neither a good nor a bad thing in itself, and the decision about whether to teach with dialogue, when, and with whom needs to be made within a broader analysis of power, identity, and purpose. We think of the educational context as a generally altruistic one, devoted to promoting freedom, the open expression and exploration of ideas, and personal as well as group development and advancement—for all participants. But when these matters are viewed within a recognition of diverse styles of communication,

diverse identities, and, most of all, diverse political interests and purposes, good intentions derived from even the most progressive sentiments no longer suffice. Suddenly, dialogue reappears as a potentially quite restrictive, possibly even hegemonic norm and constraint. The educational purposes of promoting mutual understanding, tolerance, and empathy, while clearly of value, may not be the overriding ideal in all circumstances. The interests of all students may not be servable all at the same time. One's own self-image as a teacher, with one's own identity, interests, and purposes, may come into question as well.

Several specific problems, then, arise for educators: First, how can a normative framework for dialogue accommodate diverse cultural styles of expression? If one's goal is to encourage participation in a joint communicative process of discovery, it seems contradictory to insist that this must occur on one's own terms. If one's goal is to encourage cross-cultural understanding and empathy, it seems contradictory to insist that others must adopt one's own preferred discursive styles (or even one's own language). On the other hand, without some shared basis of communicative norms, how can any engagement take place at all?

Second, as Iris Young (2002) has pointed out, there is a difference between *deliberative* and *activist* modes of communication. Deliberative communication is oriented toward reasonable engagement, negotiation, compromise, and a fair exploration of all sides of an issue. Activist communication is about making a point that needs to be made, even if it is rude, disruptive, and impolite. The goal is not to persuade but to challenge, to confront the other. To insist that such activist utterances be converted into the careful, balanced language and the reasonable tone of a deliberative engagement is to miss what is important about utterances such as speech acts; it is to defuse them of part of their purpose and impact. In pedagogical dialogue, the reasonable and deliberative mode is for obvious and mostly legitimate reasons privileged; the activist mode is not oriented toward the aspirations of understanding and consensus, which dialogue generally pursues. But even in pedagogical settings, these sorts of activist challenges, between student and teacher or between students, have a place and a potential educational value.

Third, returning to Alison Jones's point, when is it legitimate for educators to allow some groups to withdraw from dialogue with others, to segregate into culturally similar and like-minded groups in which they do not have to encounter others? She argues for the creation of separate spaces in the classroom where members of particular groups can speak safely with others who share common experiences and backgrounds, where they do not have to explain themselves to others or reeducate them at the cost of their own effort and trouble. Educators often invoke goals like "dialogue *across* differences," which assume that the purpose of dialogue is to achieve connections of understanding and agreement—which may be worthy goals in many educational settings but cannot be taken as always unproblematic, even when they spring from good intentions (see Burbules & Rice, 1991).

Fourth, as Huey-li Li (2004) and others have pointed out, there is the issue of silence. Many critics regard the issue of silence either through the lens of asymmetrical power (groups or individuals are "silenced") or as a pointed refusal to participate, as active withdrawal from participation. Li wants to argue instead for the *expressive* possibilities of silence—it is not the opposite of speech, but rather, silence and speech form a "continuum." There are different kinds of silence, she points out, and those truly interested in cross-cultural understanding need to take on the burden of hearing what these different kinds of silence might mean. Forcing others to speak, to articulate what they think and feel in explicit words, is in Li's phrase "silencing silence," and she means this as a rebuke to well-intended teachers who believe that they are serving the interests of those groups by "privileging their voices" or continually pressing them to speak up and contribute. Silences are of different types and mean different things. As Li makes it clear, assaying silence and deciding whether it is educationally pernicious or beneficial requires attention to numerous cultural and situational specifics, and it cannot be diagnosed with broad, dichotomous categories (either one "has voice" or one "is silenced"). A significant question here, then, is this: How can a teacher know *what kind* of silence she or he is dealing with? *Whose* silence is a cause for concern, and why? Li's central point is that our tendency to denigrate silence, or to see it automatically as a sign of some deeper problem, overly valorizes the chatty dimensions of participation; and in this sense, it poses a substantial challenge to the ways we think about dialogue.

The critical analyses presented here regard the development of dialogical relations as itself a political project, one in which there may be good reasons to resist or question even the terms and conditions

of dialogue itself. But at the same time, politics is always *for* something, and it is difficult to imagine any conception of social justice that does not at some level seek dialogue and more open, responsive communicative relations as an end point—even if in the short term encouraging dialogue is not the best way to pursue it. Hence, even challenges to dialogue must entail, at some level, a commitment to dialogue itself.

Disciplinarity

Disciplinarity, with the contested forms inter-, cross-, and multi-, is the approach to an academic field of knowledge through disciplines, which are conceptualized as being discrete, bounded, academic traditions of knowledge creation and knowledge dissemination. The term *subject*, also *knowledge field*, is used instead of *discipline* when the subject area is defined for or focused on a purpose (e.g., in compulsory education syllabuses, for projects addressing a problem requiring multiple approaches, and in teaching and the scholarship of teaching). This entry discusses the history of disciplinarity, types of discipline-based knowledge, and challenges to the boundaries of disciplines and the disciplinary structure of higher education.

With roots in the medieval university, maintained by prestigious learned societies, and strengthened by research funding and evaluations based on peer review, the appellation "discipline" carries connotations of prestige, tradition, mastery of knowledge and also of students, and, more darkly, control. A discipline, as a disciplined community of disciples, thus came to be distinguished from a subject area, which, rather, is often regarded as a field of study open to all and to any approach. A discipline is more often seen as working within and controlling what Kuhn called a "paradigm"—setting the research agenda, the appropriate methods, and the personnel who are equipped to work within it.

Discipline-based knowledge has been categorized as "hard" or "soft"—where "hard" means having tightly agreed-on theory and methodology, and a rule- and law-based research agenda (e.g., mathematics), and "soft" means tolerance of multiple approaches, methodologies, and models of argument, explanation, and evidence (e.g., the humanities). It has also been categorized as "pure" or "applied," where "pure" is discipline driven and shaped by its research agenda (e.g., physics) and "applied" is one where accreditation and purpose rest outside the university (as is the case with medicine). So education and its contributing disciplines, such as educational psychology and sociology, are "soft–applied," and philosophy is "soft–pure."

The sociolinguist Bernstein influentially divided knowledge processes into three sites: (1) of *production*, where new knowledge is constructed and positioned (e.g., in disciplinary research); (2) of *recontextualization*, where new knowledge discourses are appropriated and re-embedded to become educational knowledge (forming the basis of curricula and assessment); and (3) of *reproduction*, the classroom where teaching and learning take place. Such a model underlies calls for research-informed or research-based teaching.

Disciplines also have been studied as intellectual "tribes": as communities of academics, identified by citation and cocitation practices in research journals, concerned with researching and teaching historically distinct subject areas and developing, validating, peer-reviewing, and disseminating discrete bodies of knowledge.

Further light also has been thrown on disciplines by analyzing the different knowledge-making processes and academic literacy practices displayed in their top journals, for example, by analyzing arguments, the use of evidence, the authorities cited, and so on. Such academic literacies and discourse studies are concerned to render transparent the disciplinary rules (rhetorical, epistemological, stylistic, and presentational) that those seeking to enter must follow. Thus, academic literacies are important for research students who must conform, but their status is contested by those who see education as a process of equipping students to transform knowledge and who see disciplines as potentially transformational rather than merely as transmitters of knowledge: The "writing in the disciplines" movement, for example, influentially argued that the discipline is made by each writer of that discipline, professor and student alike; from this perspective, a discipline is viewed not as an institution but as a knowledge-creating community, and academic writing is regarded as knowledge- and meaning making, not merely a knowledge-demonstrating and -disseminating process.

Disciplinary studies also generate argument about the state and status of particular areas of knowledge, for example, in cases where a discipline crosses boundaries or encompasses very different knowledge-making traditions. Area, cultural, gender, and many other studies cover specific disciplinary knowledge areas but may encompass a variety of disciplinary approaches, including "pure" and "applied," experimental and theoretical, and convergent and divergent methodologies.

Challenges to the hegemony of disciplines come from those funding research on deep or so-called wicked problems, where innovative thinking is required and where inter- and cross-disciplinary approaches are favored. (All these are contested terms; *interdisciplinarity* can usefully be seen as combining and using research methods, forms of inquiry, and agenda from any discipline; *multidisciplinarity* is teamwork drawing on researchers from several disciplines; and *cross-disciplinarity* is applying the methods or agenda of one discipline to the knowledge base of another.)

Finally, there are challenges to the disciplinary structure of higher education, from those who see the university as a site of transformation rather than of transmission of academic knowledge and from educationalists concerned with Freirian, critical, or other "liberating" pedagogies. Such scholars want to move away from disciplinary organization, which they see as producing a constricting and a reproducing environment. There are two radical education-based disciplinary models that have emerged within the field of higher education and have implications for both disciplinary epistemology and pedagogy: "threshold concepts and troublesome knowledge" and "signature pedagogies." The first challenges academics within disciplines to build the curriculum around the sequential comprehension of threshold concepts (these not only are core concepts, but they are ones that challenge contemporary viewpoints and thus can be disturbing to the student, who might prefer to stay with his or her existing disciplinary paradigm). The second challenges academics to define their discipline as a set of professional practices, similar, for example, to law and medicine, which are defined not by subject content but by the core practice, which must be taught and in which students must qualify. Such a focus on disciplinary processes—writing, teaching, learning, assessment—models those who work within a discipline as sharing a common craft, as forming a "community of practice." (This is a model from cognitive anthropology—an approach within cultural anthropology that uses the methods and theories of the cognitive sciences—that returns academics to their medieval origin as a "mastery," a *maiestri*—a guild of masters.)

Conclusion

The contemporary field of educational practice tends to deal with disciplines as academic areas and academic communities held together by common interests and processes (e.g., teaching and setting assessment criteria, learning outcomes, curricular agenda, and priorities) rather than by a common epistemology. Disciplines are seen as academic research communities with gatekeeping and peer-review duties and responsibilities; and academic identity is seen as rooted in and fostered, or constricted and enervated, by disciplinarity.

But as knowledge has become deregulated, with investment in open science and with knowledge being produced outside the university, academic

identity faces the risk of becoming more fragmented. Perhaps this will force the focus to shift back to disciplines as academic homes, as communities of academic, pedagogic, and epistemological practice.

Discourse Analysis

The study of discourse has a long and deep history and can be traced to language philosophers and social theorists such as Mikhail Bakhtin, W. E. B. Du Bois, Michel Pêcheux, and Ludwig Wittgenstein. Both a theory and a method, discourse analysis in educational research grew out of the traditions of ethnography of communication and interactional sociolinguistics, and the study of social signs and signification (semiotics). Researchers in these traditions are concerned with how discourse (defined as language and other forms of social information or meaning transmission) is used in context to accomplish educational practices. This entry discusses the varieties of discourse analysis and how they are used in education to study the way social patterns in society are reflected within schools.

There has been much scholarship in educational research that includes discourse analysis; indeed, teaching and learning are communicative events, and it stands to reason that discourse analysis would be useful to analyze the ways in which texts, talk, and other semiotic interactions are constructed across time and contexts. Discourse studies and educational research are also both traditions that address problems through a range of theoretical perspectives. Many of the problems that are addressed have to do with inequality and power. Discourse analysis provides the conceptual and methodological tools for addressing the complexity of educational practices in an increasingly globalized world.

Discourse analysis has been set to work within the field of education on a variety of topics, from educational policy, teacher education, and literacy education to science, math and technology education, educational media, language policies, and academic discourses. Discourse analysis takes as its object of study any meaning-making mode (image, speech, gestures, writing, three-dimensional forms) and draws on analytic methods to understand the relationships between discourse processes and social practices. And while various traditions have different orientations, they have similar views about discourse. That is, discourse is viewed as a multimodal social practice, situated within social, historical, and political contexts. Discourse both reflects and constructs the social world and cannot be restricted to a description of grammatical forms stripped from the function and contexts in which it belongs. Discourse analysis attends to the discursive practices that constitute communicative events as well as the larger systems of meaning—or the social practices—that are constructed, transformed, or resisted through these practices.

There are many varieties of discourse analysis, including narrative analysis, building tasks analysis, public-consultative discourse analysis, critical discourse analysis, positive discourse analysis, multimodal discourse analysis, cognitive approaches to discourse analysis, and so on. To explore some of the diversity that exists within discourse studies, the next section presents some of the most common approaches to discourse analysis in educational research.

Narrative Analysis

Jerome Bruner reminds us that we narrate our experiences, choosing protagonists, listeners, and readers and situating ourselves at the nexus of the past, present, and future. Narratives can be oral or written and can take the form of a variety of genres, such as letters, legal testimony, dance, and memoir. Approaches to narrative analysis are concerned with how, through narratives, people represent their goals, stances, and ideas and, in turn, construct the world. Catherine Kohler Riessman suggests that there are four models of narrative analysis: (1) thematic analyses, (2) structural analyses, (3) interactional analyses, and (4) performative analyses.

A thematic analysis includes a focus on the content of the narrative. This approach is often useful to examine the variation between narratives among a group of narratives about the same topic. The second model is a structural analysis, which has a stronger focus on how the story is told, rather than what is told. Examples of structural analysis vary depending on the form of the narrative. For example, many narratives fit a temporal story form and can be analyzed by William Labov and Joshua Waletsky's method of identifying clauses and their functions, but others do not fit this temporal form and need different frameworks based on how the narrative is constructed through the linguistic choices of the teller. An interactional analysis focuses on the interaction between the teller and the listener, and along with theme and structure, the collaborative nature of the telling is also a point of interest to the analyst. An example of this approach is found in Stanton Wortham's approach to narrative analysis. Finally, performative analysis is an approach that sees the interactional nature of narrative tellings as a performance of identity. The objective of narrative theorists is to understand how the properties of narratives are used (or function) in the creation of self and identity.

The Building Tasks Analysis

James Gee's tradition of discourse analysis, referred to as a "building tasks" analysis, draws on American anthropological linguistics, social discourse theories, and cognitive psychology. Arguably, this approach popularized discourse analysis in educational research more than any other tradition. Gee introduced the distinction between "discourse," with a lowercase *d*, or language bits, and "Discourse," with an upper case *D*, or the sociopolitical uses of language. He brings this theory to life through five related theoretical frames and a set of building tasks that illustrate how language ties to the social world.

The theoretical frameworks are (a) *situated meanings*, (b) *cultural/discourse models*, (c) *social languages*, (d) *intertextuality*, and (e) *figured worlds*. These are the social and cultural frameworks for understanding how people use language to accomplish social goals. *Situated meanings* evokes Bakhtin's notion of genres and dialogues and refers to how people make words mean something—and that meaning has historical significance and is connected to other meanings. *Cultural/discourse models* are the storylines, narratives, and explanatory frameworks that circulate in a society. *Social languages* refer to grammar and the function of language as it allows us to express socially situated identities and relationships. *Intertextuality* refers to how texts are drawn on and rearticulated within or across social practices. And *figured worlds* are the kinds of mental models that shape how people make sense of the world.

The building tasks are tools that bring the theoretical frameworks to life and include (a) *significance*, (b) *activities*, (c) *identities*, (d) *relationships*, (e) *politics*, (f) *connections*, (g) *sign systems*, and (h) *knowledge*. As people interact, they are building social relations, identities, activities, and knowledge with and through language. The building tasks are entry points that aid the analyst in constructing meaning from a network of discourse patterns. For example, *significance* indicates the ways we use language to assign meanings to things and people and make them relevant to the conversation. *Relationships* refer to how people interact with other people, texts, or Discourses. *Identities* are the ways in which language is used to create roles for particular people and make those roles important in the social space of the interaction. Each building task has a set of associated questions that guides the analyst. The discourse analyst sets out to understand how linguistic resources are used to accomplish social goals.

Critical Discourse Analysis

Critical discourse analysis focuses on how discourses are constructed as well as how they enact social relationships and social identities, with particular attention paid to dominance/oppression and liberation/justice. Some varieties of critical discourse analysis are rooted in Michael Halliday's systemic functional linguistics. This is a theory of language

that operates on the understanding that meanings are always being invented (vs. being inherited) and that people are actively creating meanings and have choices among representational systems from which to make meanings. According to systemic functional linguistics, as people create meanings, they draw on textual, ideational, and interpersonal resources. The textual organizes discourse into recognizable patterns or social practices. The ideational enacts ideas about the world from a particular perspective. The interpersonal enacts experiences of reality. Norman Fairclough's translation of these resources is genre, discourse, and style, or "ways of interacting," "ways of representing," and "ways of being," respectively. This tripartite schema is used in educational research to study how power, privilege, liberation, and justice are represented in educational spaces. A new wave of scholarship called positive discourse analysis focuses on liberation, agency, and justice instead of domination and oppression.

Multimodal Discourse Analysis

Discourse analysis has been critiqued for its emphasis on written and spoken texts as the source of meaning, often to the neglect of meanings made in other modalities. In many cases, the reach of language is insufficient for the representational work that needs to be accomplished. Teaching and learning are multimodal activities as people draw on an array of modalities, including verbal conversation, gestures, emotions, movement, rhythm and music, and composition, to make meaning. Charles S. Peirce classified signs according to the characteristic of the relation that they have to what they represent. Modes might be iconic, indexical, or symbolic. Gunther Kress views discourse as constructed through signs and symbols and as a form of social practice. The goal of multimodal discourse analysis is to describe, interpret, and explain the ways in which meaning is constructed and understood through multimodality. Multimodal discourse analysis examines the form and function of discourse and action to understand how designers (meaning makers) position themselves and are positioned by others.

New and Lingering Criticisms

Discourse analysis has blossomed in educational research. Some of the common critiques of discourse analysis are listed below. It should be noted that educational researchers using discourse analysis have addressed some of the long-standing critiques about discourse analysis:

- There is an unequal balance between social theory and method.
- Analysis tends to be decontextualized, not attending to discourse histories and trajectories.
- Social ideologies are read onto data rather than revealed through the data.
- There is an overemphasis on domination and oppression versus liberation and freedom.
- There has been little attention to learning and the nonlinguistic aspects of interaction, such as emotions and activity.

These criticisms might be seen as a point of departure for continued scholarship in the field.

Discovery Learning: Pros and Cons

Many names have been given to the methods of teaching that emphasize teaching and learning practices that actively engage students in, and help them make sense of, what they are learning; but *discovery learning* is the term that most often is used to describe such methods. The foundations of discovery learning can be traced back to the work of John Dewey about a century ago, Lev Vygotsky in the 1930s, and Jean Piaget in the 1950s; and this approach to learning

looms large in the contemporary constructivist movement. Both Dewey and Vygotsky postulated that children learned best by actively constructing their knowledge through social interaction rather than merely absorbing ideas directly. Piaget proposed that optimal learning occurs when an opposing viewpoint challenges the previous knowledge of an individual. In the 1960s, Jerome Bruner (1967) contributed work that supported the benefits of discovery learning; he found that students understood concepts better and remembered them longer when they discovered these concepts for themselves. This entry discusses what takes place in discovery learning, the ideas behind it, evidence of its effectiveness, and the advantages and disadvantages of the approach.

While the term *discovery learning* is often used as an "umbrella" term to refer to teaching and learning methods such as inquiry-based, problem-based, Socratic, or Moore method instruction, it is not intended to capture all of the characteristic features of the individual frameworks. This is also not to imply that each of these methods is equivalent. Discovery learning, however, does embody the commonality inherent to these methods in that discovery learning emphasizes a student-centered approach to instruction that engages the learner in thinking deeply about the subject under investigation. Discovery learning can be defined as a teaching and learning model in which students learn to recognize a problem, search for information relevant to the problem, develop a solution strategy, and logically justify the strategy. Five characteristics are identified by the National Academy of Sciences as essential to discovery learning models (in the sciences). It is essential that the student learner (1) be engaged by scientifically oriented questions, (2) give priority to evidence, (3) formulate explanations from evidence, (4) evaluate explanations in light of alternative explanations, and (5) communicate and justify the proposed explanations (Committee on Development of an Addendum to the National Science Education Foundation Standards on Scientific Inquiry, 2000, p. 25).

Discovery learning can be done as an individual exercise or, more commonly, as a collaborative effort in which students are immersed in a community of practice and solve problems together. In discovery learning, the instructor acts as a facilitator or mentor to guide and pace student learning and interactions. Focus is placed on students' ideas and contributions to their own learning—the model recognizes students as active learners or collaborators, developing a deep and connected understanding of their subject, as opposed to a more passive student role as receivers of knowledge transferred to them from their instructors. The instructor also creates a classroom environment conducive to the discovery learning process by modeling what behavior is appropriate and expected as students work toward devising solutions to problems.

Thus, instructors who employ discovery-based methods have created classrooms that appear markedly different from those of their teaching colleagues (Laursen, Hassi, Hunter, Crane, & Kogan, 2010). Typically, in a classroom where discovery learning is taking place, students are involved in creating knowledge together. They are immersed in their subject, creating hypotheses or conjectures, collaborating with peers, and discussing and challenging one another's ideas. While the instructor is always available to guide and to facilitate, students are empowered to discover and to grow in knowledge either independently or together. In fact, at secondary and university undergraduate levels, discovery learning has been shown to be effective in developing students' problem-solving and communication skills (Chin, Lin, & Wang, 2009).

An essential elucidation of the ideas underlying methods such as discovery learning is found in the educational research report *How People Learn* (National Research Council, 2000, p. 68). This report promotes the concept that effective teaching strategies should incorporate some levels of metacognitive activities. These strategies are related to discovery learning in that they involve students questioning their own knowledge and understanding along with scrutinizing other students' conjectures, ideas, and solutions. Evaluating and monitoring self-progress is also a desired characteristic among students. Discovery-based methods involve the learner as an active participant in her learning, thus fostering the enhancement of metacognition skills.

Evidence in Support of Discovery Learning

Researchers investigating mathematics courses at the undergraduate level have noted that while students enrolled in a discovery-based differential equations class were better at solving conceptually oriented problems, there was no statistical difference between the two groups of students on procedurally oriented problems, in spite of the fact that this was entirely the focus of the lessons in the traditional classes. A supplemental study one year later returned similar results. This indicated that

a discovery-based learning experience might have enduring effects on students' conceptual understanding (Kwon, Allen, & Rasmussen, 2005). This study is pivotal in indicating that while one might not initially perceive a difference between traditional and discovery-based students' performance on procedural questions, conceptual understanding could still differ between the two groups. Mark Daniels (2008) also found similar results with using discovery-based methods in a study of undergraduate Calculus I and II classes designed specifically for preservice secondary mathematics teachers.

A number of other studies showed increased mathematical content knowledge related to the use of discovery-based methods. It was found that reading, in conjunction with writing and talking, can serve to further students' understanding of mathematical ideas through inquiry-based activities. In addition, a six-month study of teaching and learning mathematics in a classroom of fifth-grade students provided evidence that inquiry-based teaching methods led students to reason more in the way professional mathematicians do when problem solving (Lampert, 1990).

One of the largest studies exploring discovery-based teaching methods was conducted in 62 introductory undergraduate physics courses and involved more than 6,000 students. The study concluded that students who were taught using discovery-based interactive teaching methods had an average course knowledge gain that was almost two standard deviations above that of students who were taught using traditional methods (Hake, 1998). Similar results were obtained in an investigation of a discovery-based physics curriculum, where 6th- through 9th-grade students who were taught using discovery methods outperformed 11th- and 12th-grade students in traditional classes on an assessment that measured knowledge of physics curriculum (White & Frederiksen, 1998).

Last, a comprehensive study of the effects of discovery learning practices on undergraduate students enrolled in mathematics courses at four universities found that while the changes in beliefs, motivations, and strategies were modest for students in both the discovery and the nondiscovery-based classes, evidence suggested that the two types of courses had opposite effects on students in relation to confidence and collaboration. While students in the discovery classrooms displayed mostly positive effects in these two areas, the changes in the nondiscovery-based courses were negative in effect.

Discovery Learning: Pros and Cons

While various authors indicate that discovery learning leads to increases in both student engagement and content relevance, some have pointed out that this teaching method is not for everyone. Thus, to conclude, a list of pros and cons of discovery learning is provided based on the existing literature.

Research on discovery learning claims the following advantages. Discovery learning

- promotes creative thinking;
- sees failure as a natural and, at times, essential step on the way to success;
- is engaging and motivational to the student learner;
- promotes the development of higher-level thinking skills;
- enhances the confidence of the learner in the learning process; and
- develops skills in students that are needed for the workforce, such as problem solving, communication, collaboration, and presentation skills.

Some researchers point out that not enough is known about what constitutes good discovery-learning practices. For example, debate about how much guidance should be offered by the instructor (as facilitator) to students is unanswered (Kirschner, Sweller, & Clark, 2006). Some report that inquiry- or discovery-based design models are not easy to implement, since student learners need to quickly develop or possess a number of cognitive skills and must be inherently motivated to learn the material under investigation (Jong & Joolingen, 1998). A lack of such skills could result in ineffective student performance when subjected to discovery methods. In this regard, some of the representative criticisms of discovery learning practices are as follows:

- Not all learners embrace discovery learning as an effective or pleasant way to learn.
- Some students become frustrated easily when subjected to discovery practices.
- Some students do not feel comfortable collaborating with others or with the prospect of presenting results in front of a class, as is often an expectation of discovery-based classes.
- Instructors may be reluctant to try discovery methods, fearing that student or administrator evaluations of the instructor's teaching may not be high.

Distributed Cognition

The term *distributed cognition* was introduced by Edwin Hutchins and Tove Klausen (1998). The term refers to a general finding by Hutchins and others that it is useful to consider cognitive accomplishments as achievements of systems that include individual persons interacting with each other and with other subsystems. An analysis that assumes distributed cognition identifies something that is accomplished by a system and develops an explanation of how that accomplishment is achieved. Such an analysis can focus on information that is used and/or constructed in the activity that results in the accomplishment. By focusing on information, the analysis would be considered a *cognitive* analysis. By focusing on a system with multiple sources and sites of processing information, the cognition that is analyzed is a *distributed cognition.* This entry describes distributed cognition, examines some examples, discusses the idea that there are different levels of distributed cognition, and explains the classroom implications of distributed cognition.

Analyses that assume distributed cognition are part of a program of research, including theoretical development, that stands in contrast to the standard theory. For example, work by Walter Kintsch and Teun A. van Dijk (1978) and Allen Newell and Herbert A. Simon (1972) treated cognition as individual processes that occur in individuals' minds. Other branches of this broad development include embodied cognition, as described by Raymond Gibbs (2006) and Mark Johnson (1987) and presaged by John Dewey (1916, chap. 11); cultural-historical activity theory, as presented by Yrjö Engeström (1999); and situative theory, in the work of James

G. Greeno (2011). Each of these developments expands the focus of analyses of cognition beyond the processes that occur in the minds of individuals. Embodied cognition includes bodily movements and gestures as inherent components of thought and communication; activity theory and situative theory adopt *activity systems* (systems that can include multiple individual persons along with other material and informational resources) rather than individual mental systems as the primary focus of analysis.

Ship-Positioning System as Distributed Cognition

As an example, consider an analysis by Hutchins (1995) of the process of fixing the position at sea of a naval ship. This process was carried out at least once every hour in the open sea and at least once every 15 minutes when the ship was within sight of land. The purpose of taking a fix was to construct information about where the ship was and where it was headed. The information was represented as a region on a chart that resulted from drawing three straight lines that intersected, forming a triangle, which probably contained a point that corresponded to the position of the ship, and a line segment that represented the path of the ship in the next interval of time assuming its current speed and heading.

The process began when an officer, the bearing timer-recorder, announced that it was time to take a fix. Then, the seamen on the deck of the ship used instruments called alidades to sight prespecified landmarks. The instrument, aimed at a landmark, provided a numerical representation of the direction from the ship to the landmark. The seaman reported that representation, using a telephone line, to the officers in the navigation room. An officer, called the plotter, had a chart that represented the geography of the general location of the ship, including the locations of the landmarks. That officer drew a line, called a line of position, corresponding to the direction from each landmark to the ship. If the readings were all exactly accurate, the three lines of position would intersect at a point, which would represent the ship's location. In practice, the three lines intersected to form a triangle, a region of points that probably included a representation of the ship's position. If the triangle was small enough, the fix was considered to be satisfactory.

Hutchins's analysis of this system used the information processing framework of analyzing cognition. Overall, the system constructed symbols (numerals and lines on the chart) that were understood to provide an approximate representation of the ship's position in a spatial environment at the moment when the bearing timer-recorder officer declared that it was time to fix the ship's position, and the path the ship would take in the next interval of time if its course was maintained without change. The process included obtaining information through interaction with objects in the world—subsystems that included a seaman, an alidade, a landmark, a chart, and so forth.

By focusing on the construction, communication, and transformation of *information*, Hutchins's analysis is an example of an analysis of *cognition*. There were several sources of information and sites of knowledge that supported the representation and transformation of information; therefore, the system is an example of *distributed cognition*. By identifying the information processing components of the system and their functions in the overall process of constructing a representation of the ship's position and future path, and by showing how the activities of the components interacted, Hutchins provided an explanation in the form of an information processing *mechanism*.

Other Examples of Distributed Cognition

Hutchins and Klausen (1998) introduced the term *distributed cognition* to characterize their findings in an analysis of an incident in which the members of an airplane cockpit crew requested and succeeded in obtaining clearance to change their altitude. Different members of the crew contributed different items of information that collectively represented the conditions that needed to be met for a change in altitude to be justified and approved. Hutchins concluded that this exemplified a type of situation where the knowledge base needed for success in an activity is distributed across the participants in an activity system.

An earlier example of an analysis of distributed cognition was provided by Jean Lave, Michael Murtaugh, and Olivia de la Rocha (1984), who conducted an ethnographic analysis of some individuals as they were shopping for groceries. A cognitive process that is prevalent in shopping is decision making, when a person chooses which of several packages to buy. Lave contrasted her observations of shoppers deciding between alternatives with the then standard cognitive analyses, treating making a decision as a kind of problem solving. She concluded

that the cognitive theory of problem solving could not explain the problem-solving processes of the people she observed. The standard cognitive account assumed that a problem solver carries out a search in a problem space that remains stable as the problem solver seeks a series of problem-solving actions that achieves the goal. Instead, the problem-solving that Lave observed involved dynamic interactions of shoppers with the material and information in the store, so that the goal of the problem and the means of satisfying it were co-constituted by the shopper and the features of the environment.

Another example was provided by Sally Jacoby and Patrick Gonzales (1991), who studied the activities of a physics laboratory group ethnographically. Members of a research group require expertise to develop innovative research, and Jacoby and Gonzales focused their analysis on contributions to the physics group's activity that reflected expertise by members of the group. They found that expertise was distributed between different participants, with one participant (the senior physicist who was the group's director) providing special expertise regarding theoretical issues and another participant (a postdoctoral researcher) providing special expertise regarding the experimental literature. Jacoby and Gonzales's analysis showed ways in which participation in the group was organized to recognize and utilize expertise, and it showed that positioning that recognized expertise did not reside consistently with a single participant but shifted appropriately between participants, supporting contributions that provided the group with beneficial information and interpretations.

Toward a Pluralism of Theories at Different Levels

Analyses of distributed cognition are alternatives to analyses of cognition as a process of individual mental activity. Scientists often strive to develop a single best theory of the phenomena they study, and this tendency easily leads researchers to treat theories of individual cognition and theories of distributed cognition as competitors. An alternative, however, is to consider theories of individual cognition and theories of cognition in activity systems as being focused at different levels and to treat them as complementary. This idea has been discussed extensively by Sandra Mitchell (2003), who argued that theoretical development, especially in biology, can be understood well by considering it as *integrative pluralism*. If we adopt this view, we can consider theories of individual cognition, as they are developed in cognitive science, and theories of distributed cognition, as they are developed in studies of activity systems, usually with multiple participants, as being about the same processes but focused at different levels, treating cognition as an aspect of individual mental activity or as an aspect of processes of activity systems. There should be competitive theoretical development at each of the levels, and it is an advantage for a theory at either level to contribute to integration between theories at the two levels.

Classroom Implications of Distributed Cognition

When we consider cognition as a distributed process, we can shift the way we consider processes of teaching and learning in classrooms. Instead of only considering students as recipients of the knowledge and understanding provided by a teacher and other sources, including textbooks, it is also natural to consider knowledge and understanding as being co-constructed by the teacher, students, and other resources that the teacher and the students utilize.

When teachers and students interact, they can organize their interaction in several ways. In a common pattern, the teacher speaks, and the students listen and occasionally ask a question for clarification. In another pattern, the teacher poses a broad question or an open-ended problem and leads or orchestrates a discussion in which the students propose ideas, expand on them or question each other, and resolve differences. Theoretically, the idea of distributed cognition applies to any of the ways teachers and students organize their interactions. The patterns of information that are constructed in the classroom interaction are understood, in this view, as being co-constructed in the joint actions of the several participants.

The way participation is organized in a classroom affects what students learn. As Lave and Wenger emphasized, learning by an individual in a community of practice can be a transition from being a peripheral participant to fuller participation. When students are positioned in classroom activity as contributors to advancing the class's understanding and knowledge, and their contributions are framed as having general significance, they can learn to act in ways that are general and generative (Boaler, 2002; Engle, 2006; Engle, Nguyen, & Mendelson, 2011).

Diversity

Social diversity—with respect to race, ethnicity, religion, nationality, sexual orientation, gender, social class, and various dimensions of culture—is important for a number of reasons. First, in a diverse society, it is highly likely that social policies, reforms, educational interventions, and the like will affect different groups differently—an intervention that benefits some groups may harm others. In this context, a second set of issues arises, namely, the contentious matters of social justice, equality of opportunity, and personal and community rights. Third, even social interaction in workplaces, organizations, and institutions is shaped by diversity—members of some groups are at a disadvantage when dealing, for example, with banks, school administrators, the police, or persons above or below them in an organizational hierarchy. Furthermore, the specific details concerning diversity and its effects vary around the world.

Given the complexity of the issues raised by diversity, this entry must of necessity limit itself. It discusses some of the contentious issues within the confines of an illustrative case study, namely, the situation in the United States, where demographic changes are making racial and ethnic diversity especially significant in the field of higher education.

On the basis of the 2010 census, the U.S. Census Bureau projects that the United States will be a "minority–majority" country by 2043, with non-Hispanic Whites making up less than half of the total population. For children under 18, it is projected that non-Hispanic Whites will be a minority by 2023. The pipeline for increased racial/ethnic diversity is already in place, even without taking into account immigration, which will also continue to produce greater diversity. For the first time in its

modern history, more non-White than White babies were born in the United States in 2011.

One of the effects of this increased racial/ethnic diversification of the country will be on higher education institutions. It is estimated that by 2050, the racial/ethnic composition of community colleges will be more than half Latinos, a quarter Whites, slightly less than 10% African Americans, and 10% Asian-background students. Four-year public institutions will have slightly less than half Latinos, 8% African American students, 15% Asian-background students, and a third White students. Only in private four-year institutions will the majority of students be White (see the documentation in Lopez, 2006, p. 11).

One might ask, with these projections, why higher education institutions need to do anything to engage diversity educationally. Why is there a challenge of ensuring that students from different backgrounds in the United States and from other countries interact with each other? Won't such diverse interactions be a natural social consequence of the greater diversity that will exist on college/university campuses? The answer is "No," not if the patterns of racial/ethnic segregation that exist today continue and not if pupil assignment in K–12 continues to be based on neighborhood residency, as it is today. Unless residential segregation is markedly less than what it is today and unless students do not attend largely racially/ethnically homogeneous elementary and high schools, students will still come to college with little cross-racial/ethnic interaction. Even though students may see each other and even acknowledge some level of racial/ethnic and cultural difference, they likely will not know or understand each other in more than superficial ways.

The Controversial Role of Diversity

What increased racial/ethnic diversity means for higher education needs to be considered within long-standing debates about the impact of social diversity on the unity and disunity of institutions and politics. The ancient Greeks debated the impact of diversity on the capacity for democracy. Arlene Saxonhouse, in her book *Fear of Diversity* (1992), contrasts how Plato and Aristotle dealt with diversity. She argues that Plato conceived of a city-state in which unity and harmony would derive from a homogeneous citizenry, while Aristotle conceived of democratic unity as involving social relationships among citizens who hold diverse perspectives and whose interactions are governed by freedom and the rule of civil discourse. For Aristotle, it is discourse on conflict, not unanimity based in homogeneity, that helps democracy thrive. Thus, the impact of diversity on the sustainability and vitality of democracy has been debated for millennia, and it remains a contentious political issue.

If, as some people believe, the stability and viability of democracy depend on harmony and unity, diversity and multiculturalism are often perceived as threats to democratic processes. According to Arthur Schlesinger (1991), a prolific critic of multiculturalism, especially in educational settings,

> when multiculturalism means the assumption that ethnicity is the defining experience for every American, that . . . we must discard the idea of a common culture and celebrate, reinforce and perpetuate separate ethnic and racial communities, then multiculturalism not only betrays history but undermines the theory of America as one people. (pp. 13–14)

The fear that diversity may undermine the unity needed for democracy underlies the critiques of diversity offered in amicus briefs by the National Association of Scholars affirmative action cases over the past decade and in essays opposed to multicultural initiatives within schools of social work and intergroup dialogue programs (Wood, 2008). Others argue that diversity can be compatible with democracy and may even foster it when the rules of civic engagement involve genuine communication among people from many cultural, racial, and ethnic backgrounds.

Whatever the controversies about the impact of diversity, it is clear that higher education institutions will need to successfully educate a much more diverse population of students. The public mission will be, as now, to educate all students to be global leaders and active contributors to the sustaining and advancing of local and global economies and democracies.

Research on Diversity in Higher Education

Research on diversity in higher education provides some guidance about how colleges and universities can educate the increasingly diverse population of students to become local and global leaders. A new, large literature on the impact of diversity in higher education was fostered when evidence about the educational role of diversity was needed in legal cases involving affirmative action. In 1978, when

the first higher education affirmative action case, *Regents of the University of California v. Bakke*, was considered by the U.S. Supreme Court, there was scant research evidence that could be brought to bear on the contention that diversity has educational benefits. In *Bakke*, it was Justice Lewis Powell's reasoning, without benefit of a research basis, that was decisive: Diversity could be a compelling state interest justifying a narrowly tailored use of race in admissions. Cases that followed the *Bakke* decision adopted this reasoning, and since then, considerable effort has gone into providing empirical evidence about the educational role of diversity.

In the *Grutter v. Bollinger* and *Gratz v. Bollinger* cases, heard by the U.S. Supreme Court in 2003, three levels of diversity were conceptualized: (1) structural diversity, (2) curricular diversity, and (3) interactional diversity. Research affirms the importance of structural diversity—the demographic representation of students on campus. Students who attend the most diverse institutions interact the most with diverse peers. However, it cannot be assumed that the demographic diversity on campuses automatically leads to the desired educational outcomes for students. A second set of studies shows that diversity must be leveraged in intentional ways through courses—curricular diversity—and out-of-class interactions and programs—interactional diversity—to produce educational benefits. Research also shows that such institutional use of diversity is related to a wide range of positive student outcomes, among them critical thinking skills, academic self-confidence, consideration of multiple perspectives, motivation to bridge differences, and empathy for others who differ in social background and experience. Many studies also stress that peer interaction across diverse individuals and groups is especially influential.

Few of these studies, however, provide evidence that diversity courses or experiences specifically *cause* students to change in these ways. Mere evidence that students change from the beginning to the end of a course or a college experience is not causally conclusive because those students might have changed just because of the experience of being in college. True (randomized controlled) experiments are needed to demonstrate that diversity causes educational changes in students. For example, researchers from nine universities used an experimental design to assess the causal impact of a diversity course called intergroup dialogue, which leverages both curricular and interactional diversity by offering a structured curriculum based in active learning and by enrolling equal numbers of White students and students of color. The experimental design of the multi-university study enabled causal conclusions about diversity to be drawn. (See Gurin, Nagda, & Zúñiga, 2013, for a book-length presentation of this research.) The study found significantly greater change among the students receiving the experimental treatment—change that lasted for at least a year.

Thus, intergroup dialogue is one proven approach to leverage social diversity for educational benefit. While many other approaches exist across colleges and universities, most of them need this kind of rigorous assessment of impact. Going forward, higher education institutions need to make dealing positively with diversity a strategic mission in order to successfully educate an increasingly diverse student body. They must aim for an evidence-based impact of their efforts so as to produce graduates prepared to further technological and social innovation and to be leaders capable of negotiating, collaborating, and dialoguing with leaders across the world, especially those from non-Western countries, what Zakaria (2008) calls "the rising rest."

Dropouts

One of the major educational challenges in virtually all industrialized nations is ensuring that as many students as possible graduate from upper secondary or high school. For although many countries allow students to leave school prior to completing upper secondary school, a high school diploma is increasingly a minimal requirement for entry into the labor market and for further education. Students who quit school before graduation are referred to as dropouts. This entry discusses the causes and social outcomes of dropping out of school. It then examines some essential elements in programs aimed at preventing students from dropping out.

According to the Organisation for Economic Co-operation and Development (OECD, 2013), the average upper secondary graduation rate among all member countries in 2011 was 83% and ranged from 49% in Mexico to 99% in Slovenia. The graduation rate in the United States was 77%, which ranks 21st among all 34 member countries.

Graduation rates vary by several demographic characteristics. In the United States, for example, graduation rates are higher for women than for men; and there are large disparities in high school graduation rates by racial and ethnic background, with graduation rates among African American and Hispanic students as much as 30 percentage points lower than among Asian American and White students. Finally, there are large disparities in graduation rates by family background, with students whose parents graduated from college having much higher graduation rates than students whose parents failed to complete high school. The challenge of improving high school graduation rates in many schools, districts, and states in the United States will depend greatly on the ability to improve rates among the most disadvantaged populations, especially in places with large concentrations of such students.

One reason to reduce dropout rates and improve graduation rates is that dropouts suffer extensive economic and social consequences—they have difficulty finding jobs and earn substantially less than high school graduates, they have poorer health and higher rates of mortality than high school graduates, and they are more likely to engage in criminal behavior and be incarcerated over their lifetimes than are graduates. They also are more likely to require public assistance and less likely to vote. Although the observed relationship between dropping out and these economic and social outcomes does not necessarily imply a causal relationship, a growing body of research evidence has, in fact, demonstrated one (Rumberger, 2011). This suggests that efforts to reduce dropout rates would, in fact, reduce these negative social outcomes and the huge attendant costs—federal, state, and local governments collect fewer taxes from dropouts, and the government subsidizes the costs associated with poorer health, higher criminal activity, and the increased need for public assistance.

Understanding why students drop out of school is the key to addressing this major educational problem; yet identifying the causes of dropping out is extremely difficult. Like other educational phenomena, the causes of dropping out are influenced by an array of proximal and distal factors related both to the individual student and to the family, school, and community settings in which the student lives. Dropouts themselves report a variety of reasons for leaving school, including school-related, family-related, and work-related reasons. But these reasons do not reveal the underlying causes of students quitting school, particularly those causes or factors in elementary or middle school that may contribute to students' attitudes, behaviors, and school performance immediately preceding their decision to leave school. Moreover, if many factors contribute to this phenomenon over a long period of time, it is virtually impossible to demonstrate a causal connection between any single factor and the decision to quit school.

Interventions to Reduce Dropout Rates

Despite this difficulty, two types of factors have been identified that contribute to or increase the likelihood that students drop out of school: (1) individual factors, associated with students' attitudes, behaviors, and experiences, and (2) contextual factors, associated with students' families, schools, communities, and peers.

Knowledge about why students drop out suggests several things about how to design effective intervention strategies. First, because dropping out is influenced by both individual and institutional factors, intervention strategies can focus on either or both sets of factors. That is, intervention strategies can focus on addressing the individual values, attitudes, and behaviors that are associated with dropping out, without attempting to alter the characteristics of families, schools, and communities that may contribute to those individual factors. Many dropout prevention programs pursue such *programmatic strategies* by providing would-be dropouts with additional resources and support to help them stay in school. Alternatively, intervention strategies can focus on attempting to improve the environmental contexts of potential dropouts by providing resources and support to strengthen or restructure their families, schools, and communities. Such *systemic strategies* are often part of larger efforts to improve the educational and social outcomes of at-risk students more generally.

Second, because dropping out is associated with both academic and social problems, effective prevention strategies must focus on both arenas. That is, if dropout prevention strategies are going to be effective, they must be comprehensive, providing resources and support in all areas of students' lives. Because dropouts leave school for a variety of reasons, services provided for them must be flexible and tailored to their individual needs.

Third, because the problematic attitudes and behaviors of students at risk of dropping out appear as early as elementary school, dropout prevention strategies can and should begin early in a child's educational career. Dropout prevention programs often target high school or middle school students who may have already experienced years of educational failure or unsolved problems. Instead, early intervention may be the most powerful and cost-effective approach to dropout prevention.

To conclude, successfully addressing the dropout problem will require both capacity and will. Capacity requires technical expertise to develop and implement effective dropout prevention and recovery programs as well as more ambitious systemic school reforms. While some schools have such capacity, in most cases additional resources, technical expertise, and incentives are required to restructure existing schools. The development of such capacity will require political will; but even with the will to reform schools, it is unlikely that any country will ever be able to ensure that all students graduate from high school without ensuring adequate resources for families, schools, and communities.

Du Bois, W. E. B.

William Edward Burghardt Du Bois (1868–1963) was an African American sociologist, philosopher, historian, and activist whose work greatly influenced education in the United States. His philosophy of education is inseparable from his conceptions of the intersection of race and culture and from his view of humanity as a synergy of dissimilar cultures in a dynamic relationship of mutual benefit and interdependence. Although his philosophy of education is often perceived as captured in the "Talented Tenth" concept (the view that higher education should develop the potential of the most able Black students), that idea is only a phase in his educational thought and a particular reaction to the assaults on Black higher education at the turn of the 20th century. His overarching philosophy of education was much broader, more complex, and more progressive than the Talented Tenth theory.

Du Bois's educational thought derived from his view of civilization as a dynamic equilibrium, a

cultural ecosystem, in which humanity is preserved and advanced by insights and contributions from a diversity of cultures existing on a plane of equality. His study of race and culture was closely linked to his deeply held belief that humanity is a cultural ecosystem of different racial/cultural groups bound together by "a common history, common laws and religion, similar habits of thought and a conscious striving together for certain ideals of life" (Du Bois, 1897a, p. 10). Put another way, the separate and distinctive historical experiences of various populations produce novel ways of thinking, distinctive values and beliefs, and different preferences on a variety of political, economic, and social issues. Du Bois's philosophy of education presupposed a universal humanity sustained and advanced through the synergy and interdependence of the various racial/culture groups of the world.

The critical questions for Du Bois, then, were how different cultures of the world could achieve self-realization and how they could contribute their crucial "ideals of life" to universal humanity. His answer to the first question was relatively straightforward: "by the development of these race groups, not as individuals, but as races" (Du Bois, 1897a, p. 10). "For the development of Negro genius, of Negro literature and art, of Negro spirit," wrote Du Bois (1897a), "only Negroes bound and welded together, Negroes inspired by one vast ideal, can work out in its fullness the great message we have for humanity" (p. 10). He characterized a second and more complicated question as the struggle for cultural citizenship. Du Bois (1973) stated specifically that it was his larger goal "to educate the Negro into the possibility of full citizenship in the modern world of culture" (p. 85). Whereas self-realization was basically an internal struggle, cultural citizenship was fundamentally an external struggle, hinging directly on the power relationships between subordinate and dominant groups. The end of the Negro's striving, said Du Bois (1897b), "is to be a co-worker in the kingdom of culture" (p. 196). The long-standing contradiction between cultural self-realization and cultural oppression constituted for Du Bois the "unreconciled strivings" to be both Negro and American. Reconciliation would come only when the striving for cultural equality was achieved.

As Du Bois developed his thinking about culture and education, he also clarified his thinking about who should be educated and for what purpose. In 1920, Du Bois, rather than advocating liberal education for the Talented Tenth and industrial education for the masses, cautioned that education must seek to provide "the utmost possible freedom for every human soul" (p. 208). The aim of education, Du Bois maintained, is to "develop human souls" and "to make all intelligent" by discovering the special talent and genius of each individual. Unless education accomplishes its goal of developing "wider, deeper intelligence among the masses," said Du Bois, "democracy cannot accomplish its greater ends" (p. 208). Every single human being, said Du Bois, deserves "college and vocational training free and under the best teaching force procurable for love or money" (p. 212). Ultimately, he defined higher education as the birthright of the masses, not just a privilege of the Talented Tenth. "We assume that only the wealthy have a real right to education when, in fact, being born is being given a right to college training," wrote Du Bois in 1920 (p. 216). College training was necessary to achieve Black cultural self-realization and also to prepare Black students to engage other cultures of the world in the realm of a broader humanity. As Du Bois stated in 1920,

> Shall we teach Latin, Greek and mathematics to the "masses"? If they are worth teaching to anybody, the masses need them most. Who shall go to college? Everybody. When shall culture training give place to technical education for work? Never. (p. 215)

He viewed cultural training as the foundation of our larger humanity and thus emphasized its equal importance to the masses and elites.

The concept of a united humanity synthesized from the special gifts of each historical race remained an article of faith for Du Bois. Even the worst of times could not shake his basic belief in the prospects of a peacefully united humanity resting on the interplay among more or less coequal cultures. Throughout his life, he fought for cultural realization and cultural equality as the necessary basis for that humanity. Thus, in his 92nd year, before the 1960 Conference of the Association of Social Science Teachers, Du Bois reaffirmed his lifelong struggle for cultural realization and cultural equality. "What I have been fighting for and am still fighting for," said Du Bois, "is the possibility of black folk and their cultural patterns existing in America without discrimination; and on term of equality" (Du Bois, 1973, p. 150). It was forever his belief that African and African American art, literature, religion, philosophy, and history contained critical insights about human oppression and freedom, embodied

crucial ideals of life for all humanity, and offered the only path to a successful future for Black Americans. Beyond every group's own cultural realization, however, lay what Du Bois considered to be the highest stage of development, "the chance to soar in the dim blue air of a common humanity." Up there "above the smoke," he said, "across the color line I move arm and arm with Balzac and Dumas," "I sat with Shakespeare and he winces not," "I summon Aristole and Aurelius," and "they come all graciously with no scorn nor condescension." "So wed with truth, I dwell above the Veil," said Du Bois (1903, p. 76). Throughout his career, he believed deeply in the idea of a cultural symbiosis, a universal humanity made possible only by diverse cultural contributions.

This conception of society as a cultural ecosystem in which each separate and distinct ethnocultural group made its own distinctive and worthy contributions to the larger humanity guided Du Bois's educational theory. A child's formative education, he maintained, should be grounded on the historically conditioned experiences and sensibilities of each ethnocultural group. With respect to the education of Black children, Du Bois called for an education system based on the history and culture, as well as the philosophies and theories, centered on the African American experience, delivered through a curriculum of history, art, literature, music, folklore, ethics, and philosophy and developed by Black scholars. Yet the primary purpose of such education is not to perpetuate "the very cleft that threatens and separates Black and White America" but to realize a broader humanity that freely recognizes human differences while deprecating inequality in opportunities for individual development. Ultimately, Black education should develop not in opposition to but in harmony with the greater ideals of the American republic so that different groups could contribute to each other those cultural and humanistic insights lacking in their own separate and distinct historical experiences.

E

Economic Development and Education

The idea that there is a connection between education and economic development has now become commonplace. Politicians refer to the importance of education as increasing the returns to income and national competitiveness in the global economy, as if the relationship between education and the economy is uncontested. It is not.

It should be said that reference to economic development was once reserved for developing countries, but in light of the Great Recession and the rise of the East Asian economies such as China and India, the question of how to achieve national economic growth now also applies to the so-called developed economies. The idea that a combination of sound education and "free" markets was all that was required for prosperity is now in doubt. Yet it is precisely this formula that underlies the major theories of education and economic development. This entry discusses the dominance of human capital theory and skill bias theory in explaining the relationship between education and the economy, criticism of these theories beginning in the early 1970s, and alternative viewpoints based on current trends in the global labor market.

The field of education and economic development has been dominated by human capital theory and the related skill bias theory, which has gained significance due to the perceived information technology (IT) economic revolution. Both these theories are optimistic accounts of the relationship between education and economic development. Derived from orthodox or neoclassical economics, they have aspired to knowledge claims that are universal. And in the case of human capital theory, its general proposition that a rise in educational quality will lead to increases in productivity and economic growth has held over time and location since the 1950s, with some exceptions. That is no longer the case, and new theories have arrived that challenge its fundamental theoretical and empirical claims. The same point can be made with respect to skill bias theories.

To understand why the relationship between education and economic development is contested, we need to go back to the formal origins of human capital theory that has dominated intellectual and policy thinking. Once we understand the anomalies in this theory, we can see why competitor theories are now being developed.

Human Capital Theory

Human capital theory posits that the better educated a person is, the more productive he or she is likely to be, for which he or she will earn a higher income (Becker, 1962; Schultz, 1961). The theory has three significant assumptions: that it is in the self-interest of individuals to pursue education because it will lead to higher economic returns, which form the basis for aspiration and a sense of progress in society; that education is fundamentally efficient because employers will not hire incompetent people; and that employers will respond to a better-educated workforce by investing in new technology to capitalize on the productive potential of a more skilled workforce.

On the basis of these assumptions, the theory can be tested through rates of income returns for

particular categories of skilled work (Burton-Jones & Spender, 2011). Rate of return analyses suggested that the theory offers universal validation for increasing investment and expansion in education, especially mass higher education.

The theory was attractive because it was consistent with a capitalist ideology in which all human beings could themselves become capitalists by investing in knowledge and skills, so dissolving at a conceptual stroke the idea that there was a fundamental conflict between capitalists and workers (Bowles & Gintis, 1975). It provided policymakers with a simple policy prescription: Provide the means for individuals to have a good general education, and they will increase their income and the nation's wealth. It also provided legitimacy for social mobility because employers will hire on merit, since it would be inefficient to do otherwise. Hence, upward social mobility can be explained through the acquisition of educational credentials and the way they can be cashed out in the labor market.

While the theory had its roots in the United States, the early human capital theorists also saw its potential with respect to less developed economies. Initially the World Bank, as the principal lender to less developed economies, took little interest in education. Gradually, an interest emerged in relation to technical and vocational education and then primary education. In 1981, the World Bank appointed George Psacharopoulos as head of its education department's research unit, and his analysis of rate of returns to different levels of education in developing countries has proved, until recently, to be highly influential. As late as 2007, two of the leading proponents of human capital theory, Eric A. Hanushek and Ludger Woessmann, were arguing in a paper for the World Bank that the "quality" of education can make a significant difference to a developing nation's notional future GDP (gross domestic product). They calculated that if the educational reforms they recommend were implemented, GDP would rise in developing countries by 5% over 20 years. The educational reforms they recommended are ideologically loaded: school choice and competition, autonomy for schools, and accountability for outcomes.

Since the advent of the latest IT-driven industrial revolution, a new form of human capital theory has taken center stage: skill bias theory.

Skill Bias Theory

Skill bias theory makes the universal assumption that the demand for skilled workers will be driven by new technology. The fundamental proposition is that the general purpose technologies associated with IT are skill biased rather than skill replacing; new technology will increase the demand for higher skills rather than replacing skills with machines. Its policy significance lies in the support that it has provided and continues to provide for the rapid expansion of university education, while assuming that technology will drive the corresponding organizational and economic changes to utilize the skills that graduates acquire. There are several accounts of skill bias theory. However, the most powerful is that articulated by Daron Acemoglu (2002), who argues that there is an endogenous relationship between new technology and the demand for skilled workers. New technologies are endogenous in that their adoption is a response to incentives; in particular, the increase in the supply of skills will lead to acceleration in the demand for higher skills. Such a view is consistent with human capital theory in that it also assumes that market mechanisms will ensure that demand will respond to supply. As Claudia Goldin and Lawrence Katz (2008) note, this approach provides an explanation for the polarization of incomes: Where there is an undersupply of skilled labor, the premium for skilled labor (e.g., graduates) will rise. In the case of the United States, Goldin and Katz argue that the polarization of income is a consequence of a lack of enrollments in four-year college programs. If there was an increase in numbers of four-year college graduates, their incomes would decline, thus reducing the polarization of incomes.

While skill bias theory may be considered a theoretical innovation that builds on human capital theory, there have been few others in the orthodox tradition. One, however, is of note, the work of David Baker (2012). He argues that education produces both minds and character that are productive in the workplace and that education has fundamentally changed the workplace. In particular, what he calls the schooled society has created "thinking and choosing actors, embodying professional expertise and capable of rational and creative behavior." These enable new forms of organization that are global and characterized by accounting and auditing frameworks, elaborate legal contracts, corporate social responsibility, human relations, and strategic planning. Baker's innovation is to provide a more developed account than that of orthodox human capital theory, which focuses on the nature of the schooled society and the way it has changed the nature of organizations.

While Baker's theory extends the notion of human capital while going beyond the formal theory, both human capital and skill bias theories continue to enjoy the confidence of policymakers. This is because they chime with the more loosely articulated but rhetorically powerful notion of the knowledge economy—the view that technical knowledge and innovation are the key drivers of the modern economy. Indeed, Gary Becker (2006), the doyen of human capital theorists, has claimed that we are now living in the age of human capital because of the nature of the knowledge economy. However, human capital theory has been under intense criticism from its early days. Now, however, there are also competitor theories that make the case for it and skill bias theory more precarious.

Criticisms of Human Capital and Skill Bias Theories

By the early 1970s, human capital theory had come under sustained criticism. In particular, it failed to take into account that wages do not reflect productivity as assumed by human capital theory. Indeed, contemporary analyses of wages and productivity show a sharp divergence between productivity and the median wage. Other factors, apart from education and skill, also determine wages; these include unionization, the minimum wage, and traditions of status that continue to affect men's and women's wages. Underlying these criticisms was a further crucial assumption of both human capital and skill bias theories—they made claims to universality that their propositions held true at all times and in all places. The point made by the critics was that we could only understand wage setting by reference to a range of national institutions. Such a view is explicit in the seminal paper by David Finegold and David Soskice (1988), in which they argued that Britain had a dual equilibrium economy based on high and low skills, respectively. However, the keys to understanding this economy were the institutions that buttressed high and low skills. In other words, universal claims regarding the education–economy relationship cannot be made because we also need to understand institutional configurations peculiar to national economies.

A further problem with human capital and skill bias theories is that they assume a relatively simple correspondence between the supply and demand for skills. However, if we take positional conflict theory into account (Brown, 2000), then it is clear that rises in the demand for credentials may not reflect technological or organizational advances but are part of a competition in which credential inflation arises because individuals with higher credentials are more likely to be employed. For positional conflict theorists, it is the best resourced that will gain because they can afford to run the long credential race.

Finally, it should be noted that neither human capital and skill bias theorists nor indeed their critics have taken into account the impact of the creation of global labor markets. The former theories have applied their notion of the universal within the confines of methodological nationalism and have not taken into account the global trends and the way they will influence the supply and demand for skilled labor.

Toward Alternative Accounts of Education and Economic Development

If it has been assumed by policymakers and orthodox economists that the IT revolution will increase the demand for educated labor, then there are four trends that raise serious doubts about this claim (Brown, Lauder, & Ashton, 2011); central to these trends is the creation of a global labor market for all except those who do "face-to-face" work. The trends are as follows: a massive rise in educated labor, especially in developing economies, raising the prospect of high-skill, low-wage work; a quality–cost revolution in which East Asian and Latin American economies can produce high-quality goods and services at low cost; and the dissemination across the globe of Digital Taylorism, in which knowledge work is increasingly routinized because the distinguishing feature of all economic revolutions is that an initial burst of creativity is followed by standardization in mass markets and that there is "war" for the services of a few defined as "talented" (typically individuals from elite universities). Paradoxically, as we now have more graduates than ever before, so leading corporations take the view that only a few are really capable of driving forward their global businesses.

Key to these trends is the way that multinational companies now source skills from across the globe, usually at the lowest possible price. This means that we are now entering a period of a global auction for skilled labor, but it is a "Dutch" or "reverse" auction in which jobs go to those with the lowest costs (Brown et al., 2011). The implications for human capital and skill bias theories are clear: The assumptions that incomes will rise as educated

labor becomes more productive, and that new technology is skill biased, are in doubt in countries like the United States and the United Kingdom where skilled labor is relatively expensive. Equally, new technology appears to be skill replacing rather than skill biased.

For less developed economies, the global auction provides a mixed analysis. As we have seen in China and India, there is an increasing demand for high-skilled workers. Furthermore, one of the key findings concerning the quality–cost revolution is that high-quality goods and services can be produced anywhere, provided there is a communications infrastructure. The days when we thought that skill formation required sophisticated institutions and traditions are over. Multinational corporations (MNCs) now have the quality control systems to ensure high-quality production in which they train their operatives. The downside is that less developed economies need to identify where they can fit into MNC supply chains, not an easy task given that MNCs are footloose: They will move production locations, typically, wherever they are cheapest. The movement of production locations from the expensive Chinese eastern seaboard into the west of China and south to Vietnam is one such example. There are many others, as observers in the United States and United Kingdom have noted. What is clear is that the kind of linear human capital analysis in which higher education will lead to high economic growth, as provided by Hanushek and Woessman (2007), is inadequate to understanding the challenges faced by "developed" and less developed economies. Underlying this point is the assumption that we do not live in the imaginary of a knowledge economy but in a world of knowledge capitalism, which, as the global auction thesis suggests, has very different effects to those imagined by proponents of the knowledge economy. This has significant policy implications for how the relationship of education to the economy is understood.

Edinburgh School of Sociology of Knowledge

The "Strong Programme" in the sociology of scientific knowledge (SSK) emerged in the early 1970s at the Edinburgh University Science Studies Unit with the work of Barry Barnes (1974) and David Bloor (1976) and was conceived as a radical challenge to the traditional conceptions of science found in both philosophy and sociology; it also has implications for science education (see Slezak, 1994a, 1994c).

The SSK undermines the traditional philosophical, epistemological enterprise and also the pursuit of science itself. If knowledge is the product of

historically contingent, "external" factors in the local social context rather than "internal" considerations of evidence and reason, then it is an illusion to imagine that education might serve to instill a capacity for critical thought and rational belief. Instead of fostering a creative mind and intellectual understanding of the world, Collins and Pinch (1992) recommend that science education should attend to the social negotiation, "myths," and "tricks of frontier science" as "the important thing" (p. 150). Above all, the relativism inherent in social constructivist theories makes it impossible for teachers to offer the usual intellectual grounds for distinguishing science from nonsense. Since the rational, cognitive virtues of theories are taken to be irrelevant to their status, one cannot complain that some views are false or implausible or otherwise lacking intellectual, explanatory merit. For example, one cannot teach that Soviet Lysenkoism or Hitler's racialism were perversions of scientific truth. According to social constructivist doctrines, their success in winning consensus must count as an exemplary scientific achievement. By repudiating the role of rational, cognitive considerations as the justification for scientific beliefs, social constructivist theories are a variety of relativism that Laudan (1990) characterized as "the most prominent and pernicious manifestation of anti-intellectualism in our time" (p. x). Instead of fostering rationality and critical, independent thinking, education on the constructivist account is only propaganda, "extracting compliance" through power and influence.

The key theses of this Strong Programme are indeed so strong that they have engendered bitter controversy, and the precise wording of these claims warrants careful examination. This entry describes the Strong Programme and then examines some of the criticisms that have been made of it.

Previously, sociology of science paid attention only to things such as institutional politics, citation patterns, and other such peripheral social phenomena surrounding the production of science but had not ventured to explain the cognitive contents of theories in sociological terms. However, the opening sentence of Bloor's (1976) book asked "Can the sociology of knowledge investigate and explain the very content and nature of scientific knowledge?"—that is, "knowledge as such, as distinct from the circumstances of production" (p. 1). The failure of previous sociological studies to touch on the contents of scientific belief was portrayed by Bloor as a loss of nerve and "a betrayal of their disciplinary standpoint" because sociologists had failed to "expand and generalise" (p. 8) their claims to all knowledge.

According to the Strong Programme, sociology of science must be

> *causal*—concerned with the conditions that bring about belief or states of knowledge;
>
> *impartial*—truth or falsity, rationality or irrationality, and success or failure must be explained;
>
> *symmetrical*—the same types of cause would explain both true and false beliefs; and
>
> *reflexive*—it must be applicable to sociology itself.

Thus, Bloor asserted the appropriateness of sociological (i.e., social constructivist) explanations for all of science regardless of evaluative judgments such as truth or falsity, rationality or irrationality, and success or failure. According to Bloor (1976), sociologists were to assert their claims over the area "currently occupied by philosophers, who have been allowed to take upon themselves the task of defining the nature of knowledge" (p. 1). Indeed, Bloor (1983) proclaimed social studies of science as the new "heirs to the subject that used to be called philosophy" (p. 182). Andrew Pickering (1992) proclaimed, "The foundations of modern thought are at stake here" (p. 22). Indeed, Bloor describes the two most important modern philosophical elucidations of science as "mystification"—namely, the theories of Karl Popper and Thomas Kuhn. In the same vein, Gottlob Frege's position in the history of Western thought is generally agreed by philosophers to be second only to Immanuel Kant or even Plato. One could not cite an example of clarification and illumination that is regarded as comparable to Frege's work in the foundations of logic, mathematics, and language. Nevertheless, Bloor (1976) characterizes Frege's work as a "mystification" and as "unpromising and imprecise conceptions" (p. 93).

Bloor (1976) suggests that the "threatening" nature of any investigation into science itself has been the cause of "a positive disinclination to examine the nature of knowledge in a candid and scientific way" (p. 42). However, despite such fears of desecration and the need to keep knowledge "mystified," every philosopher since Plato has been centrally concerned with the problem of knowledge and its justification. Nevertheless, Bloor announced his intention to "despoil academic boundaries"

(p. ix) and asserted that the sociological approach to science encounters resistance because "some nerve has been touched." And, indeed, the social constructivist movement has given rise to acrimonious polemics in the academic literature. The philosopher Mario Bunge (1991) described the field as "a grotesque cartoon of scientific research" (p. 525), and David Stove (1991) characterized the sociological doctrine of the "strong programme" as "so absurd, that it eludes the force of all argument" and a "stupid and discreditable business" (p. 31). Larry Laudan (1981), who was among the first philosophers to make systematic critical analysis of social constructivism, characterized it as a "rampant relativism" and "the most prominent and pernicious manifestation of anti-intellectualism in our time" (1990, p. x). The academic disputes gained wider public attention in the so-called Science Wars (Gross & Levitt, 2004) and especially through the notorious Sokal hoax (Sokal & Bricmont, 1997). This heightening of controversy arose from the unwitting publication by the journal *Social Text* of a spoof article written in the postmodernist style by the mathematical physicist Alan Sokal, which was deliberate nonsense.

The phenomena of central interest for the Edinburgh school were "the conditions which bring about belief or states of knowledge" (Bloor, 1976, p. 4; 1983, p. 137). Bloor (1976) says, "The theoretical component of knowledge is precisely the social component" (p. 86). Bloor's idea is that our scientific theories go beyond what is directly observable (i.e., they are "underdetermined" by evidence), and what is not empirical in this sense must be shaped by sociological influences. However, the mere fact of underdetermination does not, on its own, establish any sociological claim. Some independent grounds must be given for preferring social factors as the ones that influence the "choice" of a theory but, of course, there is rarely any "choice" in this sense, since creative theory invention or discovery is best explained as a cognitive, psychological process (Thagard, 1992).

Criticisms of the Strong Programme

The extensive body of case studies has been taken to establish the thesis that beliefs have social causes, in contradistinction to psychological ones. The causal claim concerns things such as "connections between the gross social structure of groups and the general form of the cosmologies to which they have subscribed" (Bloor, 1976, p. 3). That is, the cognitive content of the beliefs is taken to be caused by contingent, local aspects of the social milieu. Bloor asserts that this causal link is beyond dispute. However, criticisms have challenged precisely the bearing of these studies on the causal claims of social determination. Steven Shapin (1979) cites the "considerable empirical achievements" (p. 65) of the SSK, but scientific discoveries always necessarily arise in some social milieu or other. Thus, it is a truism to assert, as Shapin (1979) does, merely that "culture [taken to include science] is developed and evaluated in particular historical situations" (p. 42). To the extent that social factors are indeed ubiquitous, establishing a causal connection requires more than merely characterizing in detail the social milieu, which (necessarily) must have existed. Shapin's anthropological approach postulates "homologies" between society and theories that may serve as "expressive symbolism" or perhaps function to further social interests in their "context of use." However, these don't establish the strong claims of social causation.

Bloor (1982) cites *Primitive Classification* of Émile Durkheim and Marcel Mauss (1903/1963) in support of his Strong Programme and points to their thesis that cosmologies of groups such as the Zuñi reflected precise features of their social structure. That is, society not merely influences knowledge but "is constitutive of it" (Bloor, 1982, p. 297). However, Rodney Needham (editor of Bloor's edition of *Primitive Classification*) describes the central doctrine as an unwarranted, abrupt inference without empirical basis and a logical error that flaws the entire work. Needham (1903/1963) describes the "entire venture to have been misconceived," concluding, "It is difficult not to recoil in dismay from their unevidenced and unreasoned explanations" (p. xxiii).

Bloor contrasted accounts invoking reasons, rationality, logic, and evidence (the accounts he is trying to debunk) with "the causal" model—meaning a sociological one. Bloor complained of the traditional asymmetrical rationalist approaches that they sought to explain correct scientific theories as products of reasoned thought and, therefore, not requiring resort to causal sociological explanations. Bloor (1976) regards this "teleological" approach as rendering science "safe from the indignity of empirical explanation" (p. 7), but for rationalist philosophers, good reasons are a species of causal explanation. Nevertheless, Bloor (1976) characterized the "autonomy of science" view that he is opposing as "the conviction that some beliefs do not stand in need of any explanation, or do not stand in need of a causal explanation" (p. 5). Bloor attributes

to philosophers the "teleological" view "that nothing makes people do things that are correct but something does make, or cause, them to go wrong" and that in the case of true beliefs "causes do not need to be invoked" (p. 6). By contrast with the teleological view, which inclines its proponents to "reject causality" (p. 10), Bloor defends the "causal view," that is, the sociological approach of the Strong Programme. Moreover, Bloor states, "There is no doubt that if the teleological model is true then the strong programme is false. The teleological and causal models, then, represent programmatic alternatives which quite exclude one another" (p. 9).

Laudan (1981, p. 178) suggested that Bloor's acausal view of the traditional account of belief formation has not been held by any philosopher; instead, the traditional view is that true beliefs are caused (at least in large part) by the evidence and scientific arguments that are presented. Nevertheless, in response, Bloor (1991) maintains "attacks by critics have not convinced me of the need to give ground on any matter of substance" (p. ix). Accordingly, in the second edition of his book, he says, "I have resisted the temptation to alter the original presentation of the case for the sociology of knowledge" apart from minor spelling and stylistic changes (p. ix). However, in the section on the "Autonomy of Knowledge" dealing with the problem of causation, Bloor made crucial, substantive changes concerning the very claims that had been the target of Laudan (1981; for details, see Slezak, 1994b). It is notable that the introductory text by Barry Barnes, Bloor, and John Henry (1996) neglects entirely to mention social constructivism, the Strong Programme, or the teleological view.

Bloor did address claims that psychological, cognitive explanations constitute "as decisive a refutation of the strong program as one is likely to get" (Slezak, 1989, p. 592). However, his suggestion that the Strong Programme is consistent with cognitive science cannot be reconciled with his explicit endorsement of Skinnerian behaviorism. Bloor also suggests that there is no conflict since the sociological thesis at stake is merely that there are "social aspects of knowledge" that remain untouched by the claims of cognitive science. However, the claim that there are "social aspects of knowledge" is an uncontroversial one that no one has taken issue with and not the thesis of the Strong Programme, which was advanced against traditional epistemology.

Education, Concept of

Every claim about an educational issue is partly a claim about the concept of education. The claim that there are certain "best practices" in teaching, for instance, implies that certain practices are educationally important, which implies a certain conception of what it is to be well educated. To advocate teaching a particular subject logically implies some connection between study of the subject and educational gain, and to say that a certain type of classroom management is desirable because, for example, it is conducive to developing democratic habits and values is indicative of a certain educational ideal.

It follows that everyone who engages in debate about education has to a degree a concept of education, though some are more able to articulate their conception than others, some are more able to defend and argue for their conception, while some may not even be aware that they imply commitment to a particular conception. More often than might be commonly supposed, arguments about the merits of different educational proposals are not about the likely effects of a given practice but about what has educational value; similarly, arguments about matters such as whether classics or gymnastics are more deserving of curriculum time are, at bottom, arguments about what the characteristics of educated people should be.

Relativism

The fact that there are differing and even incompatible conceptions of education naturally gives rise to the question of whether we can discriminate between these rival concepts in some rational manner. Is any concept of education as good as another, depending on who you are, where you are situated, and what you value? Or can we assert, as Plato is generally taken to have believed, that there is but one true and real concept (what he called the Idea or Form) of education, which we come to recognize by dint of rigorous philosophical inquiry (with the implication that in practice some people cannot see it and have to be guided by those who can)?

It is doubtful whether many today would defend Plato's view as thus interpreted. By contrast, most would subscribe to the view that education is what W. B. Gallie (1955) referred to as "an essentially contested concept"—that is, a concept that, generally because it is inherently evaluative, is inevitably going to be differently interpreted according to the changing values of time and place. Homeric heroes, for example, did not regard the ability to read and write as marks of the educated person, since they barely knew anything about reading and writing. But there is a danger of interpreting Gallie's notion too simplistically as implying that any conception is as good as another, provided it truly represents what you happen to value. This is unfair to Gallie, who did not argue that essentially contested concepts could be understood in any way one chooses but only that a degree of argument was inevitable in relation to certain concepts; but the argument in question is bound by certain rules and, in some cases, by facts of a nonevaluative kind. Thus, the Homeric warrior may reasonably think that martial and physical prowess are characteristics of the educated person, and we may dissent. But it does not follow that either they or we might legitimately argue that being overweight is a characteristic of the educated person.

It has sometimes been suggested that we should distinguish between a "concept" and a "conception," the former referring to something like a Platonic Form, the latter to any notion that somebody happens to hold. Thus, there is the concept of triangularity, which is the nonnegotiable notion of a three-sided figure whose angles add up to 180 degrees, whereas there may be various conceptions—that is, views, notions, or accounts, of the good life. It might prove helpful to adopt this distinction universally, but in practice, it has not been adopted, and in what follows, no distinction is made between a concept and a conception.

R. S. Peters

R. S. Peters, Professor of the Philosophy of Education at the University of London Institute of Education, who did much of his influential work in the 1960s

and 1970s, did more than anyone to sort out sense and nonsense in relation to the concept of education. Of course, as noted, philosophers who have involved themselves with educational issues may be said to have a concept of education; however, Peters's own practice implicitly made the important point that, given that fact, the appropriate, one might almost say the obligatory, first step is to articulate that conception explicitly and clearly. For this, he has been criticized as well as praised. Some, such as David Adelstein (1972), accused him of taking a Platonic stance, and of failing to see (or it was sometimes hinted, deliberately disguising the fact) that the eternally valid characteristics of the Idea of education that he claimed to discern were no more than the prejudices and values of his own background and class. Comments such as "a man might be a very highly trained scientist; yet we might refuse to call him an educated man" if he were lacking "what might be called 'cognitive perspective'" (Peters, 1966, p. 31) were castigated as being no more than a reflection of Peters's own middle-class upbringing; such criticism further tended to deflect attention away from, in this case, the important notion of "cognitive perspective" or from giving due weight and attention to various different aspects of an issue, such as the moral, the aesthetic, and the scientific. The implications of Adelstein's attack, and to a lesser extent the less personal but similar criticism of the so-called sociologists of knowledge (Young, 1971), who argue that knowledge is a social construct, logically take us back to the view that any conception of education is possible and that in itself any one is as good as another, although it is doubtful whether even Adelstein actually accepted that conclusion.

But in fact it is arguable that Peters was fundamentally correct both in his understanding of the nature of analysis generally and in his analysis of education specifically. For while it is certain that a detailed and fully fleshed-out account of what it is to be well educated will be informed and affected by the values and other nonevaluative facts accepted at a given time and place, there are certain criteria, albeit general and formal, that are necessary to any plausible or acceptable understanding of education. This may look as if it is a purely linguistic point, which is incidentally another charge that has been wrongly laid against Peters, but it is not. (Nor, more generally, should philosophical analysis be confused with linguistic analysis; though the former may take the form of the latter, it need not, and in fact even those philosophers who are widely known as "linguistic" and who did have a real interest in strictly linguistic points, such as J. L. Austin [1962] were never interested in language alone.)

Peters's argument does indeed *begin* with a linguistic point—and it is difficult to see how any conceptual inquiry could do otherwise, since it is by means of words that we refer to concepts. The English word *education* (and its counterpart in Latin, Greek, French, or whatever) cannot mean anything that you want it to mean: Being "educated" is different from being "clever," for example, though they may happen to overlap, and one is not at liberty to suggest that being educated is one and the same thing as being rich or successful. These are verbal points, but they are also facts in terms of usage at this stage in the history of the language. As such, they help us find ground on which to take our initial stand. The word "education" refers to bringing up or developing the individual in ways that we regard as desirable, but with particular reference to knowledge and the mind. The Roman poet Juvenal went further, seeing it as the development of "a sound mind in a sound body" (*mens sana in corpore sano*). But the claim here is that while one might well argue that we should develop the body as well as the mind, to regard someone as well educated who is not particularly sound of body or who is physically fit but very ignorant betrays a lack of knowledge of the English language.

From this point on, the analysis is far from merely linguistic. It will be *argued* that our capacity to think propositionally, which enables us to hypothesize, predict, and so on, and which (despite claims to the contrary) appears to be shared by no other species, is the essential characteristic of our mind and that we should develop this capacity for its intrinsic and its extrinsic value and because it is, as Aristotle put it, "our defining excellence." To develop the mind is one and the same thing as to develop our understanding.

Peters's substantive claims about education now come into play. The understanding of the educated person is not just any understanding—we would not call a pickpocket well educated just because he knows how to pick pockets successfully. More generally, we consider the educated person to be one who has more than "knowledge how to . . . ," more than a repertoire of skills, but rather has understanding of "the reason why of things." At this juncture, two points should be noted about Peters's method; he has been criticized for his use of phrasing such as "we would not call . . ." or "we would not say" on the grounds that this is simply to report on the way that he and his friends happen to express

themselves. But it is surely clear that he does not mean by such phrasing "as a matter of empirical fact nobody does say this"; rather, he means to invite readers to consider whether it makes sense to them to talk in such a way, confident in the view that honest reflection will lead to the conclusion that it doesn't make sense. Second, Peters actually tends to talk more of knowledge than of understanding. The latter can be seen as preferable since it is more open; one can understand things that are not true, for example.

On Peters's view, the characteristics of the understanding displayed by the educated person, besides involving principles of reasoning, are that it is broad, involves commitment to the standards inherent in a given type of inquiry (e.g., the scientific method), is transformative, and involves "cognitive perspective." By these terms, he invites us to consider and assent to the suggestion that being a brilliant scientist or a brilliant musician, while admirable in itself, is not the same thing as being well educated, essentially because it is a narrow proficiency, whereas we expect a well-educated person to have a range of understanding across a broad spectrum. Knowing much science but being unconcerned about the proper conduct of scientific inquiry and uninterested in whether scientific claims are legitimately grounded is another mark of a less than successfully educated person, and to acquire knowledge but allow it to rest "inert" in one's mind, available for regurgitation when required, but otherwise meaningless in that it does not inform or affect one's outlook on life in any way, is to be well informed rather than well educated. Similarly, to acquire various items of knowledge but to keep them compartmentalized in such a way that one's philosophical understanding, say, does not cross-fertilize and inform one's scientific understanding, or one's historical understanding fails to actually inform any of one's other dealings in life, is again to suggest one is well informed rather than well educated.

Of course, Peters has not proved these points in the manner of the scientist or mathematician, but then these are not scientific or mathematical claims. The question is whether, given that *education* is a value-loaded term referring to the development of understanding, we agree on reflection that these are broad conditions that we would want to write into the concept. Looked at in that way, it is hard to see who would wish to dissent—who, that is to say, would wish to argue,

> My conception of education is such that I want my children to have a narrow range of understanding, to let their knowledge lie inert, to be unmoved by the rules of scientific or philosophical thinking, and to be indifferent to the interrelationship and the illumination that various subjects may shed on each other. In my view, an educated person should be narrow of mind and unaffected by their understanding.

The final point made is that the understanding that the educated person possesses should be worthwhile rather than trivial or merely commercial. Here we enter new territory, for while few will dispute that the knowledge should be worthwhile, clearly people do dispute about what knowledge is worthwhile. Peters's approach was to argue for the importance of the basic building blocks of knowledge generation, such that educated persons are those whose understanding of things such as science, math, and philosophy empowers them to continue to expand their understanding and enables them to make wide and fundamental choices about how to live. Peters's own work was here considerably abetted by the work of many of his colleagues (the so-called London line), including Paul Hirst's (1974) work on forms of knowledge, Robert Dearden's (1968) work on autonomy, and John White's (1973, 1982) work on giving people the wherewithal to make their own life decisions.

Today, the catchphrase that most obviously encapsulates a similar conception of education is "development of critical thinking." But one must be cautious; while Peters would certainly have agreed that the educated person should be a critical thinker, many of those involved with the critical-thinking business—and this takes us right back to the beginning—appear to have given no thought to their conception of a successful education. For them, critical thinking is seen as little more than adopting a set of mechanistic procedures—devoid of reference to, and in practice divorced from, any particular range of worthwhile subject matter.

The ultimate value of having a clear concept of education is that it provides the road map for all further inquiry: Without such a concept, we do not know what would count as success and we do not know where we are going. Talk of "educational standards," for example, is meaningless unless placed in the context of a convincing conception of education. It also enables us to note subtle distinctions between education, training, and socializing, which, in turn, allow us to see that a lot of so-called educational proposals are not in fact educational at all. This is a matter of great practical importance, for failure to make such distinctions often leads people to make

suggestions that may be important but do not actually contribute to education. Teaching people to drive, for example, may be a useful thing to do but it clearly has nothing to do with educating them.

Perhaps the discussion above will lead some to say that they are not interested in education so much as, say, training in marketable skills, socialization, or developing self-esteem. But that is preferable to the current state of affairs in which we do not realize that we are arguing about different things. Distinguishing between education and socialization or training in this way also enables us to distinguish between the ideal of developing ourselves as individual persons, as human beings, on the one hand, and regarding people as merely economic or social units on the other; and perhaps most important of all, it stops us from forgetting or ignoring the former in our increasingly materialistic world.

Education, Transcendental Justification of

Transcendental arguments are basically philosophical responses to *skeptical* claims or arguments. Skeptical arguments are sweeping metaphysical claims to the effect that certain common assumptions about the world as ordinarily apprehended or experienced are either mistaken or (more commonly) without any possible rational foundation. Thus, for example, major philosophers have doubted that human agency can ever be (in any sense) free—whether (we can know that) there are other minds besides our own or, most notably, whether there is any external world of objects or facts corresponding to our apparent perception or experience of such a world. Arguments of a broadly transcendental character are a priori or conceptual claims—in other words, claims or arguments that do not depend on empirical evidence—aiming to show that such skeptical conclusions are logically incoherent, usually by virtue of assuming or presupposing what they purport to deny. An early example of this broad strategy can be found in Socrates's attempt to refute the claim of Protagoras, that since all so-called knowledge is based on subjective perception or sensation, there can be no such thing as objective (mind independent) truth. Plato points out that this (skeptical) claim seems paradoxical, since, if we agree to it, then we are effectively accepting that it is *true*—in which case, it is *false* that there is no truth.

What have usually gone under the name of transcendental arguments, however, are more commonly associated with the great Enlightenment philosopher Immanuel Kant, who sought, above all, to refute David Hume's skepticism about the possibility of objective knowledge of the world of experienced reality. Hume doubts that our experience of a world of real objects and events ordered by relations of cause and effect—or at least our claims to knowledge of this—can ever be rationally justified. Like Protagoras, he claims that it is not in principle possible to get beyond "subjective" human experience to any rationally justified knowledge of "external" or "objective" reality. Kant's classic transcendental arguments are concerned to show that any such position is riddled with incoherence and inconsistency. One major Kantian point against Hume's skepticism is that even to insist that our experience of the world is "subjective" rather than "objective" is (implicitly) to presuppose distinctions between the "subjective" or "internal" and the "external" or "objective" to which the skeptic is hardly entitled. In this regard, Kant is usually credited with having pioneered arguments (much employed by later analytical philosophers) from "polar opposites." For the skeptic to argue that *all* experience is "subjective" or

"psychological" is rather like arguing that *all* currency is counterfeit: For just as the idea of counterfeit currency relies on a contrast with *real* money, so any coherent talk of subjectivity surely presumes some contrast with what is objective or precisely *no*t subjective. Put another way, if all experience is subjective, then *none* is. At all events, Kant's transcendental arguments seek to identify or expose the conceptual presuppositions—of objectivity, identity, and causality—common *both* to familiar claims to knowledge *and* any and all skeptical doubts about the possibility of such knowledge.

In modern analytical philosophy of education, transcendental arguments have been employed—mainly, as might be expected, by educational philosophers manifestly influenced by Kant—for two main purposes: first, for the rational justification of the practice of education as such and, second, to support or justify a particular educational curricular content that prefers or prioritizes the teaching of some kinds of knowledge and activity over others. The first of these issues is given high profile by the chief architect of postwar British analytical philosophy of education, R. S. Peters, who is precisely concerned—in an explicitly Kantian way—to refute any skeptic who seriously questions the value of education. The gist of this issue—to simplify an often complex, digressive, and not notably pellucid literature—is that any such skeptical questioning of the value of education must presuppose some commitment to the human value of rationality of the kind that education is precisely in business to promote. The key point is that any serious question—such as about what one should do or how one should spend one's time—must be a request for reasons for doing this or that which demand rational and informed (or rationally informed) answers. This rather general argument about the value of reason is then (variously) developed in the direction of the second point that to be capable of serious rational response to any (skeptical or other) question one needs to be equipped with certain very specific kinds of intellectual resources of knowledge and understanding.

At all events, it is against this background that certain highly influential "a prioristic" approaches to curriculum theorizing emerged in the latter half of the 20th century. Such views were "a prioristic" precisely insofar as they saw no need to appeal to empirical contingencies—of individual psychology or socioeconomic circumstance—in order to determine the basic content of any educationally justifiable school curriculum. On the contrary, the main constituents of any defensible school curriculum could be deduced or determined—in something very like Kantian fashion—as the necessary constituents or ingredients of any conceivable *full* human rationality (insofar as reason was also held in the manner of Aristotle and Kant to have diverse purposes). Thus, on perhaps the most influential version of such curriculum theorizing—the so-called forms of knowledge thesis developed by Peters's colleague and collaborator Paul Hirst—a genuinely educational school curriculum should aim to promote the forms of logical/mathematical, natural scientific, human scientific, moral, aesthetic, philosophical, and religious knowledge and understanding (variously packaged in school "subjects") fundamental to and/or constitutive of human rationality. Although Peters's use of transcendental argument to refute the educational skeptic has attracted its fair share of criticism, it would appear that such "a prioristic" curriculum theorizing has drawn most of the fire—mainly from "poststructuralist" and "social constructivist" educational philosophers who insist (much in the spirit of 19th-century post-Kantians) that there can *be* no such necessary forms of human rationality. However, while it is likely that both sides of this case have been unhelpfully overstated, this cannot be pursued further here.

Education Production Functions

Education production functions are an application of the production function concept from economics to educational outcomes. Production functions relate the output produced to the inputs used and were first proposed as descriptions of manufacturing and agricultural processes in the late 19th century. Applications to educational outcomes and institutions began in the late 1960s. Initially, traditional economic concepts such as economies of scale were investigated, followed by estimates of economic efficiency for different educational institutions from elementary schools to colleges and universities. A major finding is that socioeconomic characteristics of students appear to influence educational outcomes more than the resources available to institutions do, although measurement problems confound efforts at general conclusions. This entry describes the development of production function techniques in economics and then reviews their application to educational outcomes at the elementary, secondary, and higher education levels.

Cost and Production Functions in Economics

The idea of production functions, in which the output produced by a production process is expressed as a mathematical function of the inputs used, was first developed in the late 19th century. A major innovation was introduced in the mid-20th century with the development of duality theory. Duality theory demonstrates that any production function with certain common mathematical characteristics will generate a dual cost function with other known characteristics. This cost function relates the cost incurred in production to the quantity of output produced and the prices of the inputs used. As a result, researchers can discover the underlying characteristics of a production technology by direct estimation of a production function or indirectly through estimation of a cost function. This allows the researcher to choose a cost or production approach based on data quality and availability.

Further development of computer hardware and econometric software in the 1960s, along with the discovery of flexible functional forms, made the estimation of production relationships feasible to a wide range of researchers. Flexible functional forms take their shapes from the data and impose minimal constraints on the shapes or characteristics of the estimated functions. Two of the most popular forms are the quadratic and the transcendental logarithmic, or trans-log, a quadratic in the logarithms. Production or cost functions of these forms were initially estimated by parametric methods based on linear regression analysis. The resulting estimated functions revealed characteristics of the underlying production technology, such as the degree of economies of scale or scope and the ease of substitution among the inputs.

Production and cost approaches both had particular strengths. Estimated production functions directly yield relationships among the inputs and the outputs but cannot be used in cases of multiple outputs. Cost functions can handle multiple outputs but require input prices to be estimated.

Development of frontier methods in the late 1970s and 1980s allowed the measurement of efficiency across establishments. Previously, cost and production functions were limited to estimates of the average or mean production characteristics of the establishments for which data were available. Frontier methods estimate the efficient production possibilities or cost frontier based on the most efficient establishments in the data and generate estimates of (in)efficiency relative to this frontier for the less efficient establishments. Economies of scale and other characteristics of the efficient frontier are also generated.

Two new econometric methods were also developed to estimate cost or production frontiers. Stochastic frontier estimation is a parametric, regression-based method that allows for deviations from the frontier due to random events as well as deviations due to differences in efficiency. Data envelopment analysis (DEA) is a nonparametric method based on linear programming that assumes that any deviations from the frontier are due to inefficiency alone. The strength of stochastic frontiers is its ability to account for random factors, but its weakness is that the estimation program may fail to converge when there are large numbers of inputs or outputs involved. DEA, in contrast, can handle large numbers of inputs and outputs but cannot account for the effects of random events. Neither method is ideal, but both methods have their proponents.

Applications to Education Production

Elementary and Secondary Education

Application of cost and production function estimation to data on schools quickly identified several fundamental difficulties. First, resources in the form of inputs or expenditures were only weakly related to measures of student achievement (output), if at all. The tendency for poorly performing schools to receive more funding, called simultaneity bias by economists, contributed to this finding. Moreover, even these weak links between resources and outcomes often disappeared when family background was taken into account. This pointed out the importance and the difficulty in measuring differences in ability and social capital across students. Unmeasured ability, social factors in the home environment, and the characteristics of peers were identified as potential contributors to these results.

Other measurement problems over and above the difficulties associated with ability measurement were also identified. The output measures, for example, are often test scores on standardized tests. These can be unreliable indicators of performance and are typically incomplete, assessing math and reading skills, for example, while ignoring science and civics. Furthermore, test scores are an imperfect measure of the *value* of education. Studies that examine the relationships between test scores and the adult wages of former students find little or no statistically significant connection.

Furthermore, simultaneity or endogeneity problems also cropped up. The observed correlation of student outcomes with teacher experience, for example, may reflect the ability of more senior teachers to choose assignments at schools with better resources or that serve higher-achieving student populations. If wealthier students stay in school longer and earn more later in life because of their family connections, independent of their education, while also demanding smaller class sizes, then a spurious correlation could be observed among school resources, educational attainment, and earnings. The attraction of stronger students to schools with greater resources could generate similar spurious associations.

Despite these difficulties, the literature on educational production grew along two paths. In the first, a single performance measure (test scores) is related to school district level inputs and student demographics. Parametric or nonparametric (DEA) frontier techniques are used to construct relative efficiency measures from the output and input data, and these (in)efficiency measures are then regressed on demographic variables. Variations in the demographic variables are found to "explain" the variations in relative (in)efficiency. Some studies invert this process, relating expenditures per pupil to test scores and demographic variables, with essentially comparable results.

The second path relates performance measures to political variables (local vs. state control, school or district choice, unionization) as well as to demographic characteristics. Variables reflecting the degree of local control and/or ability of individuals to choose among various school districts are positively related to test scores and negatively related to expenditures, leading some to conclude that competition makes schools more efficient.

Consequently, what we know about elementary and secondary educational productivity is limited and subject to many qualifications. Higher-ability or better-prepared students appear to score higher on tests. Variations in educational inputs do not appear to influence test scores or expenditures per pupil as much as do variations in the demographic backgrounds of students. Institutional settings in which households may choose among public educational providers are associated with higher test scores and lower per pupil expenditures.

Higher Education

Parallel to applications of educational production function methods to elementary and secondary schools were similar applications to colleges and universities. Initial studies of higher education, however, were not so concerned with student outcomes as with the use of resources, often emphasizing economies of scale and using output measures such as numbers of students or full-time student equivalents. Frontier methods allowed researchers to investigate the relative efficiency of higher education institutions but quickly confronted problems in measuring the relevant outputs.

Initially, this involved measurement of the teaching and research functions that led to difficulties in distinguishing quality differences across institutions. Similar measurement problems soon arose with respect to the quality of educational programs in various fields, the quality of student peers, and the value of sports and extracurricular programs, not to mention the quality of student outcomes. Input quality measurement issues also arose with respect to faculty and facilities, including dormitories.

Institutions with medical and professional schools or large numbers of graduate students further complicated efficiency comparisons.

After 2000, the emphasis of higher education production studies shifted toward student outcomes and pricing. Unlike schools in the lower grades that are often tied to geographic districts, colleges and universities operate in a differentiated product market setting over wide geographic areas in which students choose institutions for their programs as well as prices and other activities. The rising price of college educations prompted researchers to examine the performance of institutions with respect to outcomes such as graduation rates and prices rather than costs.

The diversity of higher education institutions permits little summarization of results. Community colleges are the lowest-priced institutions and may appear efficient but are lower quality. Large flagship public universities often score high on affordability and quality, but this may be due to state subsidies. Private colleges and universities often have particular programs that are high quality, or offer smaller class sizes, but their higher prices and smaller range of degree offerings often cause them to appear less efficient.

Given the public's interest in encouraging more students to pursue higher education and the difficulties in measuring quality, future research in higher education is likely to focus more on affordability (pricing) of institutions and performance measures such as graduation rates and student success after graduation.

Educational Research, Critiques of

Well-warranted critiques are fundamental to sound research. While much critique focuses on single studies or sets of studies (via peer review), the focus of this entry is on broader critiques of the field of education research, of different approaches within the field, and of recommendations for what the field should become. Different "approaches" to research can be defined variously by substantive area, by discipline, by methodology, by philosophical perspective, or by some combination of these. Sometimes, critiques of education research are explicit; sometimes they are implicit in recommendations for reform; and critiques of both types are considered here. All are historically situated, responding to a particular set of circumstances at a particular time, and are best interpreted in light of those circumstances.

During the past few decades, the nature and quality of educational research has been the subject of much debate around the world, most notably in Australia, New Zealand, Western Europe, the United Kingdom, and North America; similar issues have been aired in these diverse literatures, scholars from diverse intellectual traditions have been involved, and in many countries, the debates have become politicized. This entry will focus on a selection of key critiques (and recommendations) surrounding what has been called "the education

science movement" published between 1999 and 2012 in the United States (but many of these sources have been cited internationally and reflect themes that are prominent in debates elsewhere). The discussion will include critiques reflected (a) in the U.S. Department of Education's (ED) evolving priorities and implementation strategies, (b) in federal legislation defining "rigorous" or "scientific" research, (c) in reports from expert committees or advisory boards assembled to advise the ED and Congress at different points in time, and (d) in published responses to these documents from scholars in the field of educational research. Interrelated critiques from these various sources will be presented in a chronologically ordered narrative. Key issues underlying the debate reflected in these documents include the following: whether science or rigor can be defined in terms of particular methods; whether randomized experiments reflect the "gold standard" for education research or, more narrowly, research addressing questions about "what works?"; how the particularities of local contexts should be taken into account in conducting and using research; what role the federal government does and should play in setting research policy; how education research can be made more relevant and useful to policymakers and practitioners; and what the appropriate role of science in education practice should be.

As illustrated below, common words such as *rigor*, *utility*, *relevance*, and even *science* are used in different ways in different critiques. To understand what the word means in a given critique requires careful reading of the elaborations and examples—where they are provided. Furthermore, there are often competing interpretations of the same critique and of the phenomena that are being critiqued. The goal of this entry is to provide as fair an overview as possible of the issues reflected in a range of published critiques of education research (1999–2012), briefly illustrating those critiques with close paraphrases from selected texts and foregrounding themes and differences among them. Any evaluation of how well warranted or fair the critiques are is beyond the scope of this entry.

Critiques of Education Research From Expert Panels (1999)

In 1999, three expert panels published separate reports intended to advise ED and Congress on research policy and priorities. These reports are from the National Research Council (NRC)—an arm of the National Academies of Science and Engineering and the Institute of Medicine; the National Academy of Education (NAE); and the National Education Research Policy and Priorities Board (NERPPB)—the members of which were appointed by the secretary of education. It is important to note that the NRC and NAE panels were established by independent scholarly organizations intended to be free from political interference. While these reports had somewhat different emphases, they foregrounded many of the same themes in their critiques and recommendations. Each grounded their critiques in an acknowledgment of the potential of education research and complexity of the education enterprise to which it contributes.

The NRC panel argued that the potential of education research had not been realized: The existing research base was underused and inadequate and educational policy decisions were often based on personal experience and ideology. They noted that only a few lines of research had been sustained for the time needed to bring them to fruition. They attributed this in part to the complexity of the education enterprise and in part to underinvestment and insufficient resources, to lack of focus in research investments, and to difficulties in translating research to inform practice. Their recommendations for a strategic education research program (SERP) included the establishment of networks of researchers, in partnership with practitioners and policymakers, focused on a limited number of topics of crucial importance to students' learning. They called for combining insights from many fields, including those that addressed cognitive functioning, social processes, and organizational change, and for deploying a full array of research methods. They called as well for involving practitioners and policymakers in helping define problems, devise solutions, and monitor the effects of research-based programs to make integration of research findings a routine aspect of education practice. The SERP proposal was extended and further specified by NRC in 2003.

The 1999 NAE and NERPPB reports reached similar conclusions about the need for greater investment in education research, for a problem-focused research agenda that resulted in cumulative and sustained lines of research, and for enhancing the use of education research by practitioners and policymakers, although they foregrounded somewhat different critiques and recommendations.

The NAE report, which was commissioned by the NERPPB, raised the concerns about research that

studied students' and teachers' learning isolated from contexts and from efforts to improve educational processes. The authors explicitly criticized the linear assumption that "researchers produce knowledge about general principles, program developers apply that knowledge in design of instructional materials and programs, and local educational professionals implement those programs," citing problems of translation among these various communities. They called for a new model of the relationship between education research and improvement focused on solving specific current problems of practice and, at the same time, developing and testing general principles expected to apply more broadly.

The ED's NERPPB report, which cited the NAE report, differed somewhat from the other two reports by including "weak designs and measures" and disagreements among researchers as contributing to concerns about the adequacy and the usefulness of education research. The board called for more rigor in education research through defining appropriate research designs (that included randomized experiments and other designs involving control group methodology when randomization is not possible) and improving the quality of peer review panels and procedures. To enhance the impact of education research, they called for better means of translation and dissemination, including reliable research syntheses, for shared accountability between researchers and practitioners in improving research practice but not (at least to the same extent) for practitioners sharing in the research process as the NAE and NRC reports had done.

Implied Critiques of Education Research in Federal Legislation (1999–2003)

Federal legislation between 1999 and 2003 attempted to enhance the use and conduct of research in more specific ways than recommended by the expert panels. The 1999 Reading Excellence Act and the 2001 No Child Left Behind Act (NCLB) focused on enhancing the *use* of research: Both required those who purchased instructional programs with federal funds authorized under these acts to use programs that had been evaluated using scientifically based research (SBR). While the definition of SBR in the Reading Excellence Act was quite general—using terms like *empirical methods* and *rigorous data analyses*—the definition in NCLB was considerably narrower. The definition of SBR in NCLB named "experimental and quasi-experimental designs in which individuals, entities, programs, or activities are assigned to different conditions and with appropriate controls to evaluate the effects of the condition of interest, with a preference for random-assignment experiments." This definition has been credited with elevating randomized controlled trials to a perceived "gold standard" for education research and rigorous science, a controversial issue addressed below.

The bill proposed to reauthorize ED's Office of Educational Research and Improvement (OERI), commonly called "the original Castle Bill," shifted the legislative prescriptions regarding SBR to researchers themselves. The proposed language limited research programs that could be funded to those that fit within the bill's definition of SBR. The definition listed methods separately for qualitative and quantitative research, foregrounding experimental and quasi-experimental design for quantitative research and associating qualitative research primarily with traditions historically based in the humanities. The bill described qualitative methods as "intended to explore issues and hypotheses whose underlying dynamics and factors are not sufficiently well refined, understood, or amenable to experimental control to permit adequate study through quantitative research." Ultimately, the 2002 Education Sciences Reform Act (ESRA), which replaced OERI with the Institute of Education Sciences (IES), offered a somewhat revised definition of SBR. The ESRA contained a single definition of SBR that did not distinguish between qualitative and quantitative SBR, that called for methods to be appropriate to the research questions posed, and that limited the call for random assignment experiments (or other designs that eliminate rival explanations of effect) to research addressing causal questions. These differences have been attributed by some to the influence of a widely cited 2002 NRC Report, *Scientific Research in Education* (*SRE*).

NRC's 2002 *Scientific Research in Education*

At the invitation of the ED's NERPPB, the NRC assembled a committee to address the question of what constitutes scientific research in education. The committee published its report *SRE* in 2002. The *SRE* authors responded critically to the proposed legislation in the original Castle Bill to reauthorize OERI defining SBR in terms of methods. They argued that mandating a list of methods erroneously assumed that science is mechanistic and that

procedures can be prescribed. Against this vision, they argued that it was the self-regulating norms of the scientific community that enable scientific progress. The authors argued further that qualitative and quantitative research are quite similar epistemologically (i.e., in terms of their conceptions of knowledge), that both can be pursued rigorously, and that the research question being pursued should determine the methods used. In response to their charge, *SRE* authors offered, instead, a set of guiding principles that they argued underlie all scientific research. Those engaged in scientific research

1. pose significant questions that can be investigated empirically,
2. link research to relevant theory,
3. use methods that permit direct investigation of the question,
4. provide a coherent and explicit chain of reasoning,
5. replicate and generalize across studies, and
6. disclose research to encourage professional scrutiny and critique.

The authors highlighted the importance of attending to the particulars of contexts in addressing the extent to which theories and findings may generalize to other times, places, and populations. The report named three important types of research questions: (1) What is happening? (2) Is there a systematic effect? (3) How or why is it happening? In a cumulative program of research, only the second of these was best pursued by way of experimental designs. However, *SRE* arguably privileged programs of research that culminated in the establishment of replicable causal effects (idealized in randomized experiments) and positioned "descriptive studies" as preliminary or supplementary to this task. *SRE* also offered a set of design principles for fostering science in a federal education agency that are intended to nurture a scientific culture. Thus, the report offered policymakers an expanded and more flexible conception of science, one that locates authority for scientific rigor within the scientific community and that envisions an important role for certain types of qualitative research within a comprehensive and cumulative research agenda.

IES Critiques and Priorities (2003–2008)

While the differences between the ESRA's definition of SBR and that in the original Castle Bill have been attributed to the influence of *SRE*, the priorities proposed for the IES in 2003, articulated in the IES director's first Biennial Report to Congress (2005), appeared to give the game away. They privileged cause-and-effect studies, especially randomized experiments, and IES launched an aggressive program to increase the prevalence of such studies.

As articulated in his Biennial Report to Congress (2005), the IES director, Grover J. (Russ) Whitehurst, saw education research as badly in need of reform. Briefly citing the 1999 NRC report, he critiqued education research in terms of its rigor, relevance, and utility. For rigor, he asserted that "far too much research is based on methodologies that cannot support the questions that are addressed" and offered as general examples interpretive and qualitative methodologies and correlational studies that drew (inappropriately) causal conclusions. He then called for rigorous analyses of cause and effect using randomized trials and related methods. For relevance and utility, he called for research that addressed practical problems of policymakers and practitioners and that made results available to users in easily understood forms. Again, cause-and-effect studies were foregrounded as those most relevant and useful to practitioners.

The priorities outlined in the report to Congress were aggressively implemented within IES's scope of authority. These were reflected, per the director's reports, in funding announcements, guidelines for peer review, and funding decisions; in federally funded training programs for researchers; in guidelines for research syntheses developed by the federally funded What Works Clearinghouse, which was intended to make the results of rigorous cause-and-effect studies easily available to practitioners; and, as discussed in the report to Congress, in "differential consequences for decision makers whose choices are or are not grounded in evidence."

A 2008 evaluation commissioned by the National Board for Education Sciences (the IES advisory group that replaced NERPPB) confirmed that IES has succeeded in increasing the proportion of efficacy and scale-up studies that met the department's methodological standards for causal inquiry. This supported their conclusion that rigor had been enhanced. Thus, rigor became equated with cause-and-effect studies idealized in randomized experiments. This was a substantially different outcome from what had been proposed by the 1999 NRC and NAE panels, both with respect to the role of policymakers and practitioners and the cumulative problem-focused orientation that drew productively

on multiple methodologies. With respect to relevance and utility, the authors of the National Board for Education Science report noted increased access and dissemination but suggested that the evidence based on knowledge utilization by practitioners was insufficient to draw conclusions. The priorities and policies of IES clearly had some impact on the shape of the field and led to a new round of critiques.

Scholarly Critiques of Federal Legislation, *SRE,* and IES Priorities and Policies (2002–2009)

Following the publication of the NRC's *SRE* and the dissemination of IES's priorities, a number of scholars offered critiques of the visions of education research reflected in those documents and enacted in IES's agenda. Some saw *SRE* and federal efforts as quite distinct, with the *SRE* defending the autonomy of the scientific community against methodological prescription; others saw these efforts as part of the same federal overreach (NERPPB had funded NRC to develop *SRE*) into the practice of education research.

To provide a sense of the range of critiques, this section is organized by selected topics on which different scholars took critical positions, beginning with the role of randomized experiments in causal research, the so-called gold standard; then addressing alternative approaches to research; and finally turning to the relationships between the research community and other stakeholders (including education practitioners, policymakers, the federal government, and the public).

Critical commentaries surrounding IES priorities, federal legislation, and *SRE* were published in special issues of four journals shortly after the publication of *SRE*, and these journals have continued to publish critical commentary from time to time: *Educational Researcher* (2002), *Educational Theory* (2005), *Qualitative Inquiry* (2004), and *Teachers College Record* (2005). Readers can locate articles by proponents of various perspectives in these journals, beginning with the special issues on *SRE* cited, and searching subsequent issues for key citations (e.g., of *SRE*) or terms used in the debate (e.g., "gold standard," "scientism") or by reading one of the general reviews listed at the end of this entry ("Learning From Our Differences" or *Education Research on Trial*).

Randomized Experiments, the Gold Standard, and Causal Inquiry

One major issue that arose focuses on the extent to which randomized experiments represent a "gold standard" for causal research or scientific research more generally. Does an increase in randomized experiments signal a move toward rigor? Randomized experiments assign persons or other units of analysis randomly to groups that do and do not experience the intervention. The goal is to allow researchers to attribute postintervention differences between groups on an outcome or effect to the intervention and not to alternative factors that might otherwise explain the outcome (e.g., that the groups differed to begin with in ways relevant to the outcome).

Some read federal legislation and IES priorities as implying that randomized experiments represented the gold standard for scientific research, whereas others, including the authors of *SRE*, saw randomized experiments only as ideal for research addressing causal questions. They acknowledged that there were other ways of addressing causal questions and other types of questions that could and should be rigorously pursued with alternative methods. Some noted that randomized experiments were often difficult to mount, for both practical and ethical reasons, and called for other research designs—quasi-experiments—that used other means to control factors other than the intervention that might explain the effect. Some noted further the importance of alternative methods—survey research, qualitative methods of various sorts—to complement experimental designs supporting, for instance, questions about the extent to which an intervention was implemented as intended or about the mechanisms that led from the intervention to the effect. Some argued further that causal questions could be rigorously—perhaps more rigorously—addressed through qualitative research by tracing these mechanisms and by examining the myriad local factors that mediate the relationship between a treatment and an effect (e.g., a school's administrative policies or resources; the press for achievement evident in the school's culture).

A related issue was whether or not multimethod programs of research should be expected to culminate in causal studies of systematic effects as *SRE* was interpreted to conclude. Given the complexity of social phenomena, including those relevant to education, generalizations about which interventions "work" were seen by some, at best, as hypotheses for any given school or classroom. Examples were cited showing interventions that produced an effect in one context but failed to produce the same effect in another. To understand how an intervention works, it was argued, requires an understanding of

the sense people make of it, individually and collectively, and the ways in which it interacts with other features of their environment to shape their practice. Some questioned whether causal inquiry is appropriate at all for social inquiry, given the power of local contexts to shape understanding and practice. These scholars called for somewhat different approaches to education science or research.

Alternative Approaches to Education Research

Another key issue was whether this vision of science put forth in *SRE* adequately addresses the complexity of social phenomena. While most scholars, including the authors of *SRE*, acknowledged the importance of understanding human intent and meaning and the role of local contexts in education research, the question is what this implies about how science or research should be conceptualized. Are the generalizing goals of science (systematic effects) privileged by *SRE* adequate or even appropriate for the human or social sciences?

By offering a single set of principles that "underlie all scientific inquiry," the *SRE* panel had taken sides on a long-standing debate in the philosophy of social science about whether or not the social sciences should approach the study of social phenomena in the same way the natural sciences have approached the study of natural phenomena. For example, those who take what is sometimes called an interpretive approach to social science argue that social phenomena differ from natural phenomena because they are meaningful to the actors involved. Furthermore, meanings are seen as embedded in complex social contexts that shape (enable and constrain) what can be understood, sometimes in ways that the actors involved may not perceive. From this perspective, a primary aim of social science should be to understand what people mean and intend by what they say and do and to locate those understandings within the historical, cultural, institutional, and immediate situational contexts that shape them. This conception calls into question the meaningfulness of generalizations about what works, including how science works to inform practice! These scholars called for the development of theory that would address why and how local context matters. Conceptions of generalization or relevance should be expanded to include how researchers and practitioners could learn from always partially unique cases of practice that did not gloss over contextual differences as studies of systematic effects did.

Some questioned further the all-consuming press for SBR, arguing that the arts and the humanities, including philosophical analyses, offered important contributions to education research or scholarship and deserved more emphasis than they had received in *SRE*.

While some critiques called for diversity in the practice of education research, a different set of critiques raised the concern that fragmentation within the field limited the ability of researchers to develop a cumulative research agenda addressing key educational problems. One set of authors called for a deeper understanding of the networks through which researchers build on each other's work to enhance collective practice. Another called for data sharing to support replications. Many foregrounded the role of dialogue among researchers across different approaches to research to promote mutual understanding and collaboration and pointed to important roles for higher education and research organizations, alongside the federal government, in promoting such understandings. Some saw this as a move toward a much-needed consensus on what counts as good science; others framed the role of dialogue as providing an opportunity to learn from different approaches in addressing educational problems.

Some scholars thought that the authors of *SRE* has accepted their charge too uncritically, treating research as a neutral, technical enterprise that could provide clear answers to educational problems. Against this "white coat" view of science (sometimes referred to as "scientism"), these scholars called for a more realistic view of what scientists do and of how science influences and is influenced by education policy and practice. Some argued that scientific practice could only be evaluated from inside a particular approach or domain. This called into question the meaning of the generalizing critiques of rigor in education research writ large and even of generalizing principles, like those in *SRE*, since terms like "significant questions" or "generalizations" take on different meanings in different domains. Some raised concerns that *SRE*'s vision of science did not illuminate the ways in which scientific practice was shaped by social relations and structures inside and outside the field. *SRE*'s blanket rejection of "postmodernism" as unscientific was criticized for failing to adequately represent the meaning of the term to those whose work might be located within it and also for rejecting a constellation of approaches to research intended to ferret out issues of power and

politics. A rigorous approach to science, it was argued, can and should illuminate the social forces that shape scientific practice. Rejecting alternative approaches out of hand risks limiting opportunities for critical reflection and innovation.

Relationship Between Researchers and Other Stakeholders

A closely related set of issues focused on the relationships between the research community and other stakeholders, including the federal government, practitioners, policymakers, and public. What is the appropriate role for these stakeholders in the research enterprise? How can and should they influence the practice of research? How can and should the practice of research influence education policy and practice?

Many scholars raised concerns about the extent to which IES's priorities and policies were limiting the potential of the field of education research. By aggressively pursuing causal questions presumed to address the needs of policymakers, federal policy was diminishing resources for basic and applied research agendas that might move the field forward—including the agenda of how science actually informs policy and practice. Some saw *SRE* as complicit in federal efforts to mold scientific practice to its own ends. Others, however, saw *SRE*'s arguments as a strategic move intended to maintain an opening for alternative approaches to research in an otherwise hostile climate. Most agreed that the role of the federal government should be to support cumulative research and rigorous peer review of research proposals (consistent with the norms of scientific practice) but not to mandate methods. Some noted, however, that the selection of peer-review panels—and the methodologies with which they are familiar—could also constrain in more subtle ways the methods employed in research that is funded.

Another question concerned the role of practitioners and policymakers in the research process. Some described the press for causal studies of systematic effects as a social engineering agenda that undervalued the role of local educators. By focusing on systematic effects, it risked restricting opportunities for participation in educational decision making by those in the best position to take local circumstances into account. Echoing the 1999 NRC and NAE reports, it was also argued that involving practitioners in the research process, as collaborators and not just as consumers, was a crucial means of enhancing the relevance and the usefulness of education research.

Looking ahead, a 2012 NRC report titled *Using Science as Evidence in Public Policy* called for research on whether, why, and how science is or is not used as evidence in public policy. The framework recommended focused on a broad range of questions and methodologies to understand the complexity of the policy world; these included "understanding the assumptions underlying divergent policy framings, expert judgments, and consensus building techniques"; how practical reasoning is entailed in policy making; and how local contexts can influence the weight given to science through "institutional barriers and cultural resistance . . . and the role of moral and ethical beliefs."

Finally, a number of scholars raised questions about the appropriate role of the public alongside practitioners and policy makers in the research enterprise. These questions dealt with the dissemination and accessibility of education research, the extent to which research should inform and be informed by public debate about educational issues and solutions, and the ends as well as the means of education. Some scholars called for a public debate about the role of science in education, including questions about who gets to decide what counts as knowledge. Some highlighted the tension between scientific and democratic control of education research and practice: As education is a moral and political enterprise, its means and ends require democratic deliberation informed but not determined by science.

Evolving IES Priorities (2009–2012)

In 2009, a new director, John Q. Easton, was appointed to head the IES. This coincided with a change in administration from the conservative Bush administration to the more liberal Obama administration, which may help explain changes in emphases and tone of official policies about research.

As articulated in his first Biennial Report to Congress, the priorities Easton listed foreground relevance and usability by "developing new ways of facilitating the use of research," "building capacity in states and districts to conduct research," "developing a greater understanding of schools as organizations and how they can become learning organizations," and "creating stronger links between research, development, and evaluation." While maintaining a commitment to "rigor," the priorities cite key research questions that cannot

be addressed with cause-and-effect research alone and refer to a range of methods needed to address them. They define rigor in terms of "ensuring that the methods applied are appropriate to the questions asked and the results are valid and reliable." While this is not inconsistent with the first director's report, the elaboration of relevant methods makes it clear that rigor can encompass a wider range of methods and that these are necessary for enhancing relevance and usability. These include questions about how, why, for whom, and under what conditions they are effective. They also include questions that are not necessarily focused on interventions but those that seek to understand the characteristics of high-quality teaching; the processes of schooling through which policies, programs, and practices affect student outcomes; and so on.

These priorities appear to return to the sorts of recommendations made by the 1999 NRC and NAE panels 14 years earlier and began to address some (but far from all) of the scholarly critiques outlined above. Remaining most seriously unaddressed, it could be argued, are those critiques that call for illumination of the sociopolitical forces that shape the scientific practice and the ways in which the scientific practice both enables and constrains democratic deliberation about the means and ends of education.

Educational Science

The term *educational science* is an umbrella term, used by educationists on the Continent, that covers research on education from many different paradigms. Following Thomas Kuhn's introduction of the concept of the paradigm, which he originally applied to the natural sciences, it has gradually become increasingly common also in other branches of science to identify several paradigms, each with its own understanding of science and its own concepts and methods. Due to their differing conceptualizations of science, these paradigms cannot be reduced to each other without incurring substantial loss of elements each regarded as essential and distinctive. This has been evidenced by the controversies on positivism, hermeneutics, and systems theory in which the scientific possibilities and limits of each

paradigm have been the subject of much debate. It has become clear that scientific research can only be adequately judged within the framework of the particular scientific paradigm on which it is based. It makes no sense, for example, to use the criteria of quantitative research to assess qualitative research or vice versa. Differing aims, concepts, and methods lead to different kinds of research and insights, which help increase the complexity of scientific knowledge. Transdisciplinary research is only possible if there is reciprocal acceptance of differences between paradigms. This also applies to indissoluble cultural differences between the basic assumptions of scientific paradigms. The management of these differences plays an important role in the globalized world.

The fact that educational science consists of different paradigms leads to a complex understanding of education and science. This is exemplified by the development of educational science in Germany in the 1970s, when educational science developed through the formation of three paradigms: (1) humanist pedagogics (*Geisteswissenschaftliche Pädagogik*), (2) empirical educational science, (3) and critical educational science. This entry discusses each of these three paradigms and their significance for educational science.

Humanist Pedagogics

Humanist pedagogics began to emerge as a discipline in the 1920s, based on the works of Friedrich Schleiermacher (1768–1864) and Wilhelm Dilthey (1833–1911). As a scientific trend, it had become established in the universities and the faculties of education by 1933. Among its most important representatives were Herman Nohl (1879–1960), Theodor Litt (1880–1962), Eduard Spranger (1882–1963), Wilhelm Flitner (1889–1990), and Erich Weniger (1894–1961). After World War II, this tradition was kept alive mainly by the Göttingen school, represented by Nohl and Weniger, where many of the leading scholars of the next generation (e.g., Wolfgang Klafki and Klaus Mollenhauer) were trained. According to humanist pedagogics, the basis of all scientific and theoretical knowledge has always been educational reality and educational practice, and thus, it defines itself first and foremost not as a theoretical discipline but as a practical discipline, characterized by the elements described in the next section of the entry.

Historicity and Culturality of Education and Educational Science

Dilthey emphasized the significance of history and culture and explained how human beings can only gain an understanding of themselves by interpreting history and culture. It is only with the help of the humanities—with their orientation toward history and comprehending human culture—that human beings can come to understand and define themselves. Humanist pedagogics places the emphasis on how history and the humanities are crucial in the shaping of human beings. Following Schleiermacher, humanist pedagogues such as Nohl and Weniger and their followers reasserted Dilthey's acknowledgment of the historicity and culturality of education.

The Significance of Hermeneutics for Educational Science

Based on the works of Schleiermacher and Dilthey, humanist pedagogues became interested in the hermeneutic process of comprehension. Dilthey's attempt to develop hermeneutics as a science of text interpretation (*Textwissenschaft*) and the comprehension of the "objectifications" (or products) "of mind" (e.g., institutions, school programs, educational action, etc.) was furthered by humanist pedagogics, which focused on historical texts as a source of hermeneutic knowledge. Among these texts are the rules, school regulations, biographies, and works of the "great" pedagogues. These were considered important objects of interpretation. The aim was to grasp their meaning in relation to their original contexts and to the history of their effects up to the present day. Insofar as these texts constituted a codification of the objectifications of the mind, interpreting them was expected to help comprehend objectifications of the mind from the period of their origination up to the present day. In humanist pedagogics, this process has been described as the hermeneutics of educational reality. Humanist pedagogics has made historical reconstruction and interpretation its goals and aims to achieve an understanding of educational reality as a significant whole.

Through Clifford Geertz's reception and further development of these ideas about the role of hermeneutics and meaning, in the past few decades, they have taken on an important role in American cultural anthropology. This, in turn, has led to their exerting a great influence on qualitative empirical research in educational science, through their use

in the ethnography of education, an area that has undergone rapid expansion. The 12-year Berlin Study on Rituals and Gestures, which was initiated and headed by Christoph Wulf and included one inner-city school and four fields of socialization, is a well-known example.

The Autonomy of Education and Humanist Pedagogics

Humanist pedagogics examined the question of the relative autonomy of education and educational science from two starting points. On the one hand, Schleiermacher, Dilthey, and Nohl tried to liberate educational science from its dependence on ethics and psychology and, thus, to define it as a specific and autonomous discipline. On the other hand, the relative autonomy of pedagogics had to be defined in order to uphold children's rights in relation to adults and the social groups influencing education.

The Educational Relationship

Nohl wanted to develop a theory of education based on the personal relationship that structures the encounter between teacher and student. In the same spirit, Dilthey had already emphasized that pedagogics can only start with a description of the educator in relation to the student. Dilthey, and humanist pedagogics as a discipline, saw the pedagogical relationship as the core of education. Nohl (1949) described as the basis of education a "compassionate relationship" between "an adult and a developing young person who attains his life and shape on his own" (p. 134). Education therefore occurs in the context of a relationship that exists "for the youth." In this relationship, the educator must defend the youth's individual right to development and self-realization against unjustified external interventions. From here stems the imperative of assuming pedagogical responsibility for youths, with a view to safeguarding their interests.

Theory and Practice in Education

Weniger believed that studying the relationship between theory and practice should provide better understanding of educational practices, their theoretical and political bases, and the practical aspects of education. For him, the object was to build a pedagogical theory that focused on practice and its development. The fact that pedagogical theory takes pedagogical practice as its starting point, and that it interprets and determines it, demonstrates that educational science is in essence a practical science. Pedagogics is understood as a practice for a practice.

Empirical Educational Science

Critical rationalism, as developed by Karl Popper, had a great influence on the epistemology of empirical research. Wolfgang Brezinka, for example, drew on it widely in the program for the "development of pedagogics towards educational science" that he designed in 1972. He developed a concept of the science of education whose purpose he saw as being to acquire knowledge and not to question the conditions under which data are generated or evaluated. Scientists are expected to produce knowledge, not to shape the world or influence human beings. The goal of a science is the investigation and analysis of reality. The unity of science is assured by two elements: first, its definition of its objectives and tasks and, second, the general rules of the scientific method. Defined in these terms, science can be differentiated from other fields of human activity, such as politics, economics, education, art, and religion.

Science is thus defined as a research activity oriented toward gaining insight into reality with the aid of the scientific method. However, conceptualized in this way, educational science cannot fulfill all the tasks to be dealt with in the field of education. Brezinka therefore expanded his program of educational science; in accordance with analytical philosophy, he supplemented educational science with the philosophy of education and practical pedagogics. He then divided educational science in the broad sense into educational theory and the historiography of education. The field of educational philosophy is also subdivided into the epistemology of pedagogical statements and moral philosophy. Practical pedagogics is defined as apprenticeship.

Critical Educational Theory

Breaking clearly with the traditions of humanist pedagogics and empirical educational science based on critical rationalism, another trend in the educational science evolved out of the paradigm of the Frankfurt School of Critical Theory, developed by Max Horkheimer, Theodor W. Adorno, Jürgen Habermas, Herbert Marcuse, and later Axel Honneth. Opposed to the humanist and empirical movements, the new orientation emphasized the social and the historical character of education and relied on a critical theory of society, science, and the subject. According to this perspective, educational

science must include—in its effort to achieve a reflexive self-understanding—an analysis of the social conditions that pertain. Critical theory originated as a negation of traditional thought; its purpose was to criticize bourgeois society and its scientific activity. It helped develop reference points for education and educational science, such as the concepts of enlightenment, emancipation, reification, criticism, society, theory and practice, and recognition.

Critical educational theory strives to be a theory of educational practice that is both of and for practice and includes constant self-reflection and self-criticism. Proponents of critical educational theory, such as Klafki, Mollenhauer, and Herwig Blankertz, saw its main aim as being to establish what is possible under given social conditions in order to ensure success and constant improvement of the education process. Critical education theorists consider humanist pedagogics and empirical educational science to have deficits that leave these paradigms without a basis for conducting a critical analysis of the societal development of education. In their view, ideological criticism is needed to examine the process by which political and economic structures exert an influence on education. Ideological criticism exposes the social conditions of production and calls attention to erroneous rationalizations and the effects of the false interpretations, norms, and theories that result from a deficient understanding of the social situation and of the possibilities of intervening in this situation.

Conclusion

In cognizance of the complexity of child-raising and education, today's educational science encompasses knowledge that investigates educational reality and its deficits, takes a critical stance toward society, and is self-reflexive. It is oriented toward the hermeneutic and quantitative understanding of meaning. To do justice to the demands placed on education in the globalized world, educational science also needs to be founded on anthropology. This means including perspectives from the theory of hominization, philosophical anthropology, historical anthropology, and cultural anthropology in the conceptualization of educational anthropology. Another important task of anthropology in the globalized world is to help children and young people cope with the two major opposing trends toward homogenization and cultural diversity in the educational process.

Educational Theory, Nature of

Educational researchers usually do not give a great deal of attention to the nature of educational theory. In their research, they are focused primarily on working with particular theories that apply to

relatively delimited areas. For example, a great deal of research is done within the context of cognitive developmental theories, or theories about the relation between social class and educational attainment, and so forth, and it is merely assumed that these are *educational* theories.

Among the small number of scholars (including philosophers of education) who are interested in the nature of educational theories in general, two different and only slightly interacting traditions have evolved. One of these reflects Continental interests and ways of conceptualizing matters; the other reflects parallel influences from the English-speaking world. Addressing and comparing both approaches with the topic, this entry reconstructs several conceptions of the nature of educational theory and points to their limitations. The conclusions reached are that educational theory can barely be adequately conceptualized as a *scientific* theory and that it can only cautiously be regarded as a *practical* theory. Nevertheless, in the controversies between these two prevalent conceptualizations of educational theory, a third option has often been neglected, that is, seeing educational theory as a *constitutive* theory.

Educational theory, then, from the perspective adopted in this entry, is an attempt to conceptually constitute education as the formal object of a science of education or of educational studies. In doing so, it maps out the domain of education as a specific problem area and prepares the ground for its empirical investigation. Although a dictionary-type definition like this sounds authoritative, there is an ongoing debate about the nature of educational theory, especially about its relationship to educational practice, about the elements as well as the different types and functions of educational theory, and, finally, about the relationship between theory of education and philosophy of education. Rather than developing a particular theory of education, this entry briefly outlines some general dimensions of any educational theory. It begins by looking at Siegfried Bernfeld's definition of education as a societal response to the fact of child development and at Gert Biesta's identification of purpose, content, and process as constitutive elements of any educational theory. As indicated above, a particular focus of this outline is the distinction between a *scientific* theory, a *practical* theory, and a *constitutive* theory. Finally, it will be argued that by conceptually constituting education as a specific domain, a constitutive theory of education is able to develop a domain-specific theory of education in contrast to the approach of philosophy of education that is usually domain unspecific.

Elements of Educational Theory

Given the plurality of educational theories embedded in different historical and societal settings, talk about "the nature" of educational theory might be understood as an impossible universalistic pretension. Although a universal educational theory might, for good reasons, be unattainable, there are some elements that can be considered as the constitutive minimum of an educational theory.

According to Siegfried Bernfeld (1973, p. 32), education can be regarded as the sum total of a society's reactions to the fact of child development. This approach is universalistic and contextualized at the same time: Education is seen as a universal function of social reproduction across generations; at the same time, the responses to the fact of child development can take on different forms in different historical and societal contexts. Another aspect of Bernfeld's approach is remarkable: By regarding education as a "reaction," Bernfeld establishes that education presupposes the anthropological fact of ontogenesis, or individual development, which education takes up and directs but does not itself cause or initiate. Furthermore, Bernfeld's approach is not restricted to intentional education on the level of personal interaction but also includes functional education in institutional arrangements that are part of a society's reaction to the fact of child development. Summing up, there are at least two necessary elements of any educational theory: an anthropological element (the fact of child development) and a social element (the reactions of a given society).

Although these two elements of educational theory can hardly be disputed, the status of an approach like Bernfeld's is open to question. Does he in fact provide a theory of education or, rather, a definition of education? A nominal definition (sometimes also referred to as a reportive definition) refers to or reports the correct use of words. By nominal definitions, we can, for instance, distinguish between elves, dwarfs, and hobbits; the report can be incorrect, of course, but even if correct, the definition tells us something about language use, not about the world outside language. Another type of definition that also tells nothing about the world is a stipulation by an author that a term is going to be used in a particular way (usually as a matter of convenience) irrespective of the way in which that term is

normally used. A (scientific) theory, however, is not like this—in principle, it can be falsified, for it makes a statement about how some aspect of the world *is*. Yet how could you falsify the assertion that education is the sum total of reactions of a society to the fact of child development?

The harsh opposition between definitions and theories, however, can be conciliated. For in addition to scientific theories that can be falsified or verified (e.g., theories of moral cognitive development), there also are theories that, first of all, constitute the formal object of investigation. For example, in the 17th and 18th centuries, "childhood" was discovered as a particular field of study by constitutive theories that established childhood as a specific stage of life with its own developmental regularities. In a similar way, after the identity of state and society was dissolved, modern political theory established the political system as a functionally differentiated subsystem of society in contrast to premodern holistic conceptions of the field. Consequently, these *constitutive* theories are not simply falsified or verified but rather *differentiated* and *refined* by empirical investigations. Seen in this way, Bernfeld's theory of education is neither a nominal nor a stipulative definition, nor a scientific theory, but a constitutive theory. It reveals education as a real-world phenomenon, not by pointing at isolated interventions and events but by conceiving of education as a complex phenomenon whose generic traits are not visible or tangible and, thus, have to be theorized.

From a formal perspective, Gert Biesta (2006, p. 22) has identified three elements of any educational theory: purpose, content, and process. *Purpose* points to the fact that education implies a form of directed development of childhood in society, as opposed to mere evolution. Although the notion of purpose tends to restrict education to intentional education, one cannot do without a broad understanding of education as a directed process, which implies that this element needs to be reflected in an ethics of education. *Content* hints at the fact that any relationship between learning and teaching deals with a second factor, which is subject matter in terms of knowledge, skills, and attitudes. In premodern societies, education was mainly about learning a specific and relatively limited number of items of knowledge and skill that were considered valuable elements of a given tradition. In modern societies, this factor shifted to a meta-level so that learning to learn, or developing the disposition to gain knowledge and skills, became more and more important. In any case, the content of education also needs to be reflected with reference to normative considerations. *Process*, finally, hints at the fact that education is a specific form of mutual communication over time that takes on a reality of its own. It is not an attempt to make isolated mechanical interventions; rather, it is a process of communicating meaning that is transactional insofar as both those who are involved and the subject matter of their joint attention are changed in the very process of education. Accordingly, the process element of education needs to be reflected in a social theory that captures education as a specific order of interactions.

Although there can be no doubt that purpose, content, and process are constitutive elements of any educational theory, one can ask whether these elements really capture the specifics of education or whether purpose, content, and process are in fact constitutive elements of communicative interaction in general. If we admit that these elements characterize communication of any sort, we still have to flesh out the specifics of *educational* communication. In so doing, we see that two options open up. The first option would claim that there are specific "educational" purposes, contents, and processes. This claim faces severe problems, particularly with regard to purposes and contents. What many consider the ideal ends of education, such as emancipation or autonomy, are not exclusively educational. The same holds true for contents; since there are no contents that are in themselves "educational," the range of possible contents cannot be limited from the outset. Therefore a second option seems to be more promising: The specifics of educational communication are determined not by the elements involved but by the formal structure or grammar that combines these elements in the very process of education. In this approach, the procedural character of education gains center stage. Education is regarded as a specific interaction order that transforms both the purposes and the contents as well as the interacting partners involved in this process. Thus, it becomes clear that education, like any other complex phenomenon, is not adequately described just by listing its elements.

Theory and Practice

Any theory of education is confronted with the question of how it relates to the practice of education. In contrast to theories in the natural sciences, we can find a threefold relationship of theory and practice in education and other social studies. First, the *subject*

matter of the theory is not a natural phenomenon but a practice. Second, a theory may take the form of a "practical theory" that claims to *serve* practice, at least by reflection and analysis. Third, a practical theory may have practice as its *origin* insofar as perplexities within practice may give rise to theorizing the problems at hand. Generally speaking, the latter point is illustrated by the history of educational thought, which shows that an elaborated theory of education is a fairly late undertaking compared with the practice of education, which is as old as mankind. Only when the relationship between the generations was no longer taken for granted and the career of each individual was considered to be a matter of deliberate choice and conduct of life did a need for a theory of education arise.

This understanding of educational theory as a practical theory *of* education and *for* education was the core of the so-called *Geisteswissenschaftliche Pädagogik*, which dominated the German discourse in educational studies into the 1960s. This tradition drew a sharp distinction between sciences and humanities (*Geisteswissenschaften*), and educational studies were considered part of the latter. The notion of a practical theory, however, underestimates the difference between the status of a theory within the practice of scientific investigation and scholarship, on the one hand, and the status of a theory within the practice of education, on the other. In both cases, practitioners may have an implicit "theory" that guides their practice, and in both cases, this "practical theory" may gain some degree of explicitness; a scientific theory, however, claims to have a status different from that of a practical theory. In this vein, William James (1899/1962) has stressed that a practical theory of education is "concrete and ethical," whereas a scientific theory like that of psychology is "abstract and analytic" (pp. 5–6): "Psychology is a science, and teaching is an art; and science never generates arts directly out of themselves. An intermediate inventive mind must make the application, by using its originality" (p. 3). Thus, the divide between a universal and abstract scientific theory and the specific and concrete tasks of educational practice has to be bridged by forms of judgment.

Types of Educational Theory

The critical discussion of the pretensions of a practical theory and the rise of a positivist self-understanding of social sciences has led to a differentiation between different types of theory, particularly between a practical theory and a scientific theory. Following Émile Durkheim (1911/1956), a practical theory is located in a middle ground between a science of education and the art of education. An art is defined as "pure practice without theory," a "system of ways of doing which are oriented to special ends and which are the product either of a traditional experience communicated by education, or of the personal experience of the individual" (p. 101). An art can gain some level of reflectiveness, but for Durkheim, "reflection is not an essential element of it, since it can exist without reflection." Social sciences, like the science of education that was just emerging in Durkheim's time, deal with social facts, including (among others) those pertaining to education. A science "studies these facts to know them, and only to know them, in an absolutely disinterested fashion" (p. 93). Now, a practical theory differs from both an art and a science but takes on an intermediate role:

> Instead of acting on things or on beings in a determinate way, one reflects on the processes of action which are thus employed, not to understand and explain them, but to appreciate what they are worth, if they are what they should be, if it is not useful to modify them, and in what way, and even more, to replace them completely with new procedures. These reflections take the form of theories, they are combinations of ideas, not combinations of acts, and in this they become closer to science. But the ideas which are so combined have, as their object, not to express the nature of things as given, but to direct action. They are not actions, but are closely related to actions which is their function to orient. If they are not actions they are at least programs for action, and in this respect they are like art. (pp. 101–102)

To differentiate between a practical theory in this respect and a science, Durkheim introduces the important difference between pedagogy and the science of education. Pedagogy as defined by Durkheim includes the work of theorists such as Jean-Jacques Rousseau and Johann Heinrich Pestalozzi, as well as most of the literature of progressive education. The object of such practical theories "is not to describe or explain what is or what has been, but to determine what should be" (Durkheim, 1911/1956, p. 99). Interestingly enough, even in the tradition of analytic philosophy, educational theory is ascribed the function of determining and guiding education: "The function

of the theory is to determine precisely what shall and what shall not be done" (Hirst, 1966, p. 40).

Functions of Educational Theory

The discussion of the notion of a practical theory and Durkheim's distinction between types of theories already entailed that a theory may take on different functions. In the natural sciences, theories have a rather narrow but straightforward function; namely, the *explanation* and *prediction* of empirical facts. The Baconean understanding of theory elevates the method of inductive reasoning over that of Aristotelian logic and regards theory as the explanation and prediction of empirical facts; this view still resonates in contemporary social sciences, where, for example, the lure of evidence-based education has gained a tremendous attractiveness among researchers and politicians. Judged by the ideal of a scientific theory in the sense of a hypothesis or a logically interconnected set of hypotheses that have been confirmed by observation, the analytic philosopher D. J. O'Connor (1957) noticed that educational theory comes off rather badly. His conclusion was that in educational contexts, the word *theory* can be only a "courtesy title": "It is justified only where we are applying well established experimental findings in psychology or sociology to the practice of education" (p. 110). On the basis of O'Connor's ideal of a scientific theory, education can be regarded only as an applied field for theories of other disciplines, not as a scientific discipline that draws on its own resources for theorizing education.

Although the educational theorist Paul Heywood Hirst (1966) agreed with O'Connor that education is a "field subject" (Tibble, 1971, p. 16)—a field of practical affairs like engineering or politics that is dependent on theories from foundational disciplines—he disagreed about the function of a theory in educational contexts. Theories of science and theories of practical activities, he claimed, "are radically different in character because they perform quite different functions, they are constructed to do different jobs" (Hirst, 1966, p. 40). The former consists of judgments about what is the case, while the latter consists of judgments about what ought to be the case. For Hirst, the validity of the principles of a rational educational practice must be judged according to the criteria of the relevant foundational disciplines. Thus, for Hirst (1966), educational theory can rightly take the form of a practical theory that is aimed at constituting a rational educational practice. This practical theory, however, must be based on scientific theories provided by foundational disciplines (particularly psychology, sociology, philosophy, and history). The validity of the practical educational theory, then, can only be judged according to the scientific criteria of the foundational disciplines.

> The psychological reasons must be shown to stand according to the strictest canons of the science. Equally the historical, philosophical or other truths that are appealed to must be judged according to the criteria of the relevant discipline in each case. (p. 51)

Beyond the reasons and standards of foundational disciplines, educational theory has "nothing *educational*" (Hirst, 1966, p. 51) to appeal to.

Are there any options for theorizing education that are missed between O'Connor's positivist conception of a scientific theory and Hirst's normative conception of a practical theory? With regard to the ideal of a scientific theory, the anthropologist Siegfried Ferdinand Nadel (1957) has pointed out that "only the most advanced sciences have reached this level of explanatory theory-building" (p. 1). It cannot be precluded that in the field of education there might be scientific theories in the more ambitious sense, but even where explanation and prediction of facts seem to be attainable (e.g., in class-size research), the results are mixed, and a theory in a strict sense is not within reach. According to Nadel, however,

> *theory* can also be understood in another, less ambitious, sense, namely as a body of propositions . . . which serve to map out the problem area and prepare the ground for its empirical investigation by appropriate methods. . . . *Theory* here equals conceptual scheme or logical framework. (p. 1)

These theories are neither scientific theories nor practical theories. Instead, they could be considered constitutive theories that try to map out the problem area in question. Accordingly, a theory of education tries to define the domain of education, not as a marked-off realm of the social world—a "material object" that can be regarded as a given social fact—but as a "formal object" of a science of education that has to be constituted conceptually. The need for theorizing education in this way is apparent, since, as a material object, education is interwoven in different social processes and interactions between newcomers and grownups so

that it can be identified only theoretically or, to be more precise, identified by a constitutive theory.

The function of educational theory as a conceptual scheme differs both from the function of a practical theory and from the function of a scientific theory in a narrow positivist sense. In contrast to the latter, it does not assume that education can be regarded as a given social fact that can be explained and predicted by educational theory. In contrast to the former, a theory understood as a conceptual scheme does not pretend to direct and guide the practice of education. Mapping out the problem area is not directed at the practice of education but at the science of education, since it prepares the ground for the identification of educational problems and their empirical investigation by appropriate methods.

Nevertheless, indirectly, this type of educational theory may have a practical function as well. Not by directing and guiding education in a straightforward way but by (re)conceptualizing education, theory may identify educational problems where practitioners, politicians, and the public have seen none. Thus, theory may contribute to a different way of thinking regarding the tasks and methods of education, which is why educational theory is important not only for the practice of science itself. Because educational theory thus involves communication with practitioners, politicians, and the wider public, a "double hermeneutic" (Giddens, 1987, p. 20) takes hold, which implies that an educational theory does not capture an independently constituted social reality that continues regardless of what this theory is. Like any social theory, educational theory enters constitutively into the world it describes.

Educational Theory and Philosophy of Education

Is the above-mentioned function of a constitutive theory of education adequately captured in philosophy of education? In other words, is there a need for theorizing education independent of philosophy? The question of how theory of education relates to philosophy of education is usually not particularly prominent in the literature. Tacitly, one seems to assume that philosophy of education implies theory of education. In this vein, a handbook article on "What Is Philosophy of Education?" (Phillips, 2010, p. 4) states that "the discussion must start with the nature of philosophy itself—for it should be obvious that individuals holding different conceptions of what constitutes philosophy will give quite different accounts of philosophy of education." Especially in the English-speaking tradition, this is the common approach in philosophy of education; it starts with a detailed analysis of the question as to what the nature of philosophy might be and—in light of answers to that question—addresses the question as to what the nature of philosophy *of education* might be. Often the latter question is not treated in as detailed a manner as the former. Rather, having answered the former question, it is assumed that one has simultaneously sketched an answer to the latter question as well. This assumption is underpinned by the suggestion "that as a field philosophy of education is on par in complexity not with any one branch of philosophy, but with the *whole field* of philosophy" (Phillips, 2010, p. 17). Thus, in its scope and dimensions, philosophy of education is considered to be as broad and complex as philosophy itself. The widely felt infinity and indeterminacy of philosophy of education are finally explained by hinting at the infinity and indeterminacy of the "field" or the "domain" of education itself: "The field of education is so broad and complex, and is intertwined with so many other aspects of society, and is of such fundamental social importance, that the direction philosophical work can take is almost limitless" (Phillips, 2010, p. 17). In consequence, the dictionary-type definition of philosophy of education—"Philosophy of education is a field where philosophical inquiry is pursued that focuses upon issues arising within the domain of education" (Phillips, 2010, p. 18)—does not really have a defining character. It marks off neither a particular field of philosophical inquiry nor the domain of education itself. The dictionary-type definition, however, makes sense only insofar as it relies on the fact that everyone has an implicit understanding of what the domain of education constitutes. What is still lacking, however, is an explicit theory of education—in other words, an attempt to conceptualize education not as an empirical object but as an object of inquiry. For elucidating education, it is insufficient to hint at empirical objects such as schools, since many different processes are going on there simultaneously. How can we know that education is going on at a particular school? (Biesta, 2011, p. 190). Thus, if philosophy of education refers to the "domain" of education, this domain itself has to be conceptualized. In other words, philosophy of education cannot do without a theory of education, and the latter cannot simply be derived from the former.

Theorizing education as a task of its own, independent of philosophy but not ignorant of

philosophy and its methods, has not been prioritized for various reasons. One reason is the long-dominant so-called isms approach in philosophy of education that started from established philosophical positions from which "implications for education" were derived (Burbules, 2000, p. 10). Another reason why the task of theorizing education has not been at the top of the agenda is the fact that, at least in the English-speaking tradition, education is usually considered to be a "field subject," not a scientific discipline of its own. To be sure, the question whether education should be regarded as a field subject or as a discipline of its own cannot be resolved easily, and there are good reasons for both sides (Scheffler, 1966). These positions, however, have different implications for theorizing education: Regarding education as a field subject implies that the crucial theoretical work is done in the so-called foundational disciplines (philosophy, history, psychology, sociology), while distinctively educational sources for theorizing education are left unnoticed (Biesta, 2011). The result is that in the English-speaking tradition, there are usually numerous theories in education but a limited attention to a theory of education. In a recent expansive *Handbook of Educational Theories* (Irby, Brown, Lara-Aiecio, & Jackson, 2013), there are 100 chapters on theories coming from diverse disciplinary contexts——from behavioral learning theory to constructivist curriculum theory and organizational theory—but only one entry (by Gert Biesta) that explicitly addresses the distinctive task of a theory of education.

The Continental tradition, especially the German tradition, of constructing the field is different. Here, from around 1800 on, we find attempts to theorize education as an autonomous academic discipline, not separate from psychology and philosophy, especially ethics, but concentrating on its own "indigenous concepts"—first of all *Bildsamkeit* (formability), and the practice of education—as being the major source for a theory of education (Herbart, 1806/1989).

The broader context for the development of education as a discipline of its own is the fact that modern societies are functionally differentiated. Just as any other functional sphere, education too follows its own logic and can no longer be considered part and parcel of a premodern, all-encompassing concept of politics or ethics. That is why it was felt that a theory of education cannot simply be derived from political theory or ethics (Schleiermacher, 1826/1983). Rather, it must focus on the logic of education as a differentiated, autonomous, and universal functional sphere in modern society. Consequently, under modern conditions, one has to distinguish between a domain-specific and a domain-unspecific theory of education. The former is contextualized in a functionally differentiated society, while the latter is decontextualized and holistic, treating education as an anthropological constant.

Now, the crucial question is which type of educational theory is presupposed or developed in philosophy of education. By its very nature, philosophical inquiry tends to be domain unspecific. It is characterized by its methods but not by a specific subject matter. Although there is philosophy of science, political philosophy, philosophy of education, and so forth, philosophical inquiry always deals with meta-level questions and the types of philosophical activity—either metaphysical/speculative, normative, or analytical (see Phillips, 2010)—across the different functional spheres. That is one reason why philosophy of education usually tends to presuppose or develop domain-unspecific theories of education. Another reason can be found in the aftermath of the ancient self-understanding of philosophy as "love of wisdom" that was in fact a far-reaching educational project rather than an intellectual activity of experts. In this vein, John Dewey (1916/1985) defended a holistic understanding both of philosophy and education as being not merely intellectual endeavors but as dealing with "fundamental dispositions toward nature and fellow-men," so that he finally could define philosophy "as the general theory of education" (p. 338). No wonder that this understanding of philosophy of education has trouble dealing with education as a specific domain, in which not all predicaments of the human condition are at stake at the same time; that is, it has trouble defining the limits of education, focusing on the specific problems to which education is supposed to be the answer. Thus, the limitless nature of philosophy of education is due to a presupposed domain-unspecific theory of education, and by drawing attention to the capacity of a constitutive theory of education, it was shown that this is by no means self-evident or without any alternative.

Embodiment

The idea that the body is inextricably involved in learning has a long history. "I hear and I forget; I see and I remember; I do and I understand" has been attributed to Confucius. In his famous *Democracy and Education*, John Dewey (1958) held that "the material of thinking is not thoughts, but actions" (p. 184) (a view that reflected the influence of his fellow pragmatist William James), and Maria Montessori made much the same point when she emphasized that the hand allows the mind to "reveal" itself; Maurice Merleau-Ponty's phenomenology made much of the fact that the self is embodied (discussed elsewhere in this encyclopedia). Ideas from this pedigreed tradition have influenced both contemporary learning theory and educational practice.

In current education circles, the expression *embodied learning* has been used interchangeably with action learning, kinesthetic learning, and embodied education. In this entry, it will be understood as referring to learning that is augmented by the learner's physical movement. The strongest embodied learning occurs when these movements are congruent with key concepts in the topic that is being learned, and so the actions must be consciously designed into an educational lesson. (Congruent actions are ones that map with, or ground the content to, our sensorimotor systems. For example, spinning a yo-yo over one's head can help ground the sensation of centripetal force; tapping an icon on a touch screen to start a simulation of a yo-yo would not be a case of highly embodied learning.)

Humans are designed to process or encode information through various input channels—in the formal school day, the most common of these are visual (reading) and auditory (e.g., listening to a lecture). Although we usually are adroit at processing via these two modes, there is a movement to include more embodied learning in the classroom. Below,

various theories supporting embodied learning are listed, and the discussion will end with new technologies that can aid in presenting and exploring content via gesture or gross body movements.

Using the Body to Learn

As the pragmatist philosophers and others over the ages have stressed, our bodies are designed for action. More recently, researchers have argued that perception is not just for the static encoding of environmental features into the perceiver's mind, but rather the environment itself affords (makes possible) certain actions; and because we move, those affordances are constantly in flux. In short, human cognition is deeply rooted in the body's interactions with the physical environment (Wilson, 2002), and multiple research domains now support the tenet that embodiment is a powerful underpinning of cognition. The various domains include (but are not limited to) the following: neuroscience and mirror neurons (Rizzolati & Craighero, 2004), cognitive psychology (Glenberg, 2010), social psychology (Niedenthal, Barsalou, Winkielman, Krauth-Gruber, & Ric, 2005), linguistics (Lakoff & Johnson, 1980), mathematics (Lakoff & Núñez, 2000), gesture (Goldin-Meadow, 2003, 2009), and performing arts, such as theater and dance (Noice & Noice, 2006; Winters, 2008).

An intriguing demonstration of how cognition is intertwined with the actions of the body is found in a study where participants listened to words related to various body areas ("lick," "pick," and "kick"), and brain activation was observed in the sensorimotor areas associated with performing those actions. For example, hearing "lick" activated motor and premotor areas associated with the face and tongue, "pick" with the arm, and "kick" with the leg area. The suggestion is that we draw on our experience in the physical world not only when thinking literally about bodily actions but also when engaging in higher-order thought processes and semantics. The meanings of these words are still associated with the motor and premotor cortical areas used to perform them—even in the adult brain. This implies that if we were able to instruct people using body movements and activating appropriate sensorimotor codes while learning, then students might learn better. One mechanism to explain this may be that cognitive resources are freed by the use of the motor system, or perhaps moving the body helps strengthen the memory trace as another modality has been added during encoding.

An earlier spate of studies demonstrated a direct effect of physical enactment on cognitive processes. In the self-performed tasks domain, researchers compared participants who heard a list of unrelated action phrases with participants who performed those actions. The consistent finding was that the self-performing participants recalled more of the phrases than those who merely heard the phrases. This is sometimes called being "generative." There is increasing evidence that body movement such as gesture can serve as a "cross-modal prime" to facilitate the retrieval of mental or lexical items. If physical movement primes mental constructs such as language, then it may be that increasing an individual's repertoire of conceptually grounded physical movement will provide fertile areas from which new knowledge structures can be developed. *These gestures, however, need to be congruent.*

After a certain grade in school, the majority of the educational content in Western education is conducted using abstract symbols, namely, the symbols of language (words and syntax) and the symbols of mathematics. For these symbols to be meaningful, they must be based in something outside of the system of symbols themselves. Body perception and action, and the experiences based on perception and action, may become internalized in what has been termed *perceptual symbols*. When the appropriate sensorimotor systems are engaged, the converging inputs of perceptual symbols might work together to create stronger and more stable knowledge representations. However, it is important that the actions be congruent with the content to be learned. Performing jumping jacks in front of an interactive whiteboard will not increase knowledge about centripetal force; the perceptions and actions must be structurally or analogically related to the symbols and their meaning for effective learning to take place—what has been referred as *gestural congruency* (Segal, 2011). Thus, lengthening the string on the yo-yo must mentally map to the symbol r for radius in the equation for centripetal force. The embodied sensation that follows reinforces the concept that it is easier to spin at the same speed when the string is longer (i.e., force is decreased when r is increased).

What Role Does Technology Play?

Manipulables are concrete objects that can be used to activate real-world knowledge; but with the advent of new media and ubiquitous computers, it has become easier to virtualize them. There is no

clear answer yet as to whether using real or virtual manipulables is more effective.

However, it is possible to build on a purely embodied sensation by adding virtual components—instructional designers are now able to merge the physical with the virtual. By mapping a virtual or digital velocity vector onto the spinning yo-yo in real time (e.g., on a whiteboard behind the student), it is possible for a student to learn with both physical and virtual systems in place. This type of interactivity, the meshing of the physical and the virtual, is called *mixed reality* (MR). Paul Milgram and Fumio Kishino (1994) use the term to describe the space in between entirely virtual environments and entirely real-world environments. In the current technology landscape, this is a very broad definition that is inclusive of a wide range of applications from digital overlays on camera views, to physical objects such as simple machines interfacing with digital displays, to enhancing virtual reality interactions with haptic feedback.

Here is an example of how MR is being used in education today. Although this example uses a large-scale immersive platform, MR does not have to be big—the use of Microsoft's single KINECT sensor is bringing motion capture into informal and formal learning spaces. In addition, tablets and small form handhelds with accelerometers lend themselves to embodied designs. One large MR environment is called the Situated Multimedia Arts Learning Lab. It is a 15 × 15 foot space with interactive floor projection. It tracks a handheld wand using 12 infrared motion capture cameras. The physical body is now able to function like a 3D cursor in the immersive space. Several randomized controlled studies have demonstrated significant gains when content learned from Situated Multimedia Arts Learning Lab is compared with learning in a regular classroom. Researchers do not believe that it is the large environment that drives the learning; rather, it is the amount of embodiment designed into the lesson (Johnson-Glenberg, Birchfield, Tolentino, & Koziupa, 2013).

Taxonomy for Embodied Learning

The study of embodied learning is rapidly advancing, and the term itself is in danger of becoming blurry with overuse. It may be time to codify it with a taxonomy that applies to education. Mina Johnson-Glenberg and colleagues propose three necessary components for a range of embodied learning: (a) amount of motoric engagement; (b) gestural congruency—that is, how well mapped the evoked gesture is to the content to be learned; and (c) perception of immersion.

Emerson, Ralph Waldo

Ralph Waldo Emerson (1803–1882) was an American essayist and poet. Born in Boston, Massachusetts, Emerson was the fourth child of a Unitarian minister. He graduated from Harvard Divinity School and served as junior pastor in Boston's Second Church. After the death of his first wife, Emerson began to question his theological commitments. He resigned from his pastoral position in 1832, writing in his journal, "I have sometimes thought that, in order to be a good minister, it was necessary to leave the ministry." Emerson began a new career as a speaker on the Lyceum circuit, where traveling lectures and debates were presented before eager American audiences. Many of Emerson's famous essays grew out of these popular lectures. Emerson's early book, *Nature* (1836/1982b), served as the intellectual foundation for American Transcendentalism, a movement aimed at helping individuals develop an authentic existence in the human and natural worlds. His 1837 address to the Phi Beta Kappa Society, "The American Scholar" (1837/1982a), cemented his literary reputation and remains the most compelling statement of his educational vision. Emerson's two books of essays, the first published in 1841 and the second in 1844, span a wide variety of topics, from history and poetry to friendship and manners. His later essay "Education," which he presented at various graduation ceremonies and which was eventually published in *Lectures and Biographical Sketches* (1884), is his most explicit treatment of formal education.

Throughout his writings, Emerson is keenly concerned with the growth of the individual—the development of the individual's powers, potentials, and capacities—an emphasis demonstrating that his thought is thoroughly centered on educational concerns. Indeed, Emerson's treatment of individuality and moral perfectionism as it relates to education constitutes his greatest contribution to educational thought. "A man," he writes in his essay "Self-Reliance," "should learn to detect and watch that gleam of light which flashes across his mind from within, more than the luster of the firmament of bards and sages" (Emerson, 1841/1982c, p. 176). Education should encourage people to recognize and treasure this "gleam of light," to trust their own thoughts and impressions, and to develop their own genius. Foreshadowing later critical theorists, Emerson worried that educational efforts often simply reproduced existing power relationships and social structures. Rather than social reproduction, Emerson argued that education should instead help students to act autonomously, to develop a tapestry of powers, to avoid the life of mindless conformism, and to become creators instead of receivers. Thus, Emerson (1884) writes,

> The great object of Education should be . . . to teach self-trust; to inspire the youthful man with an interest in himself; with a curiosity touching his own nature; to acquaint him with the resources of his mind, and to teach him that there is all his strength. (p. 110)

How does one educate for individuality and self-trust? Emerson suggests that the key is to help people to have an expansive range of experiences. In his essay "The American Scholar," Emerson describes three important realms of experience that influence and shape the mind: *nature*, *books*, and *action*.

Emerson defines nature broadly, to include not only the nonhuman, natural world but also the day-to-day human world as well. Our engagement with nature, he argues, can become an avenue of self-knowledge. Emerson was intrigued by Immanuel Kant's "turn to the subject," where human beings are thought to experience nature indirectly through categories of understanding imposed by the human mind. As we study and classify nature, Emerson reasoned, we experience our own mental categories at work in the universe. It is this connection between mind and nature that grounds Emerson's Romantic spirituality. Beyond the opportunity for self-knowledge, the experience of nature is also educative because of the solitude it provides, allowing individuals respite from the demands of social conformity. Nature enriches not only our language but also our intellectual and moral understanding through the metaphors it suggests. "Who can guess," writes Emerson (1836/1982b), "how much firmness the sea-beaten rock has taught the fisherman?" (p. 59). Finally, the experience of nature educates because of how it demands the full exercise of the human senses, thus facilitating the development of individual powers.

In his discussion of books, Emerson deals with how we learn from the experiences and thoughts of others. Emerson, as a man of letters himself, valued the contribution of books and culture but thought

that they were much too heavily emphasized in schools. An overreliance on books destroys individual creativity, teaching students that thoughts come from the outside rather than from within. We should not rely on books as a source for our thoughts; rather, we should use them for inspiration. Through books we realize that we, too, can become great thinkers.

The final realm of experience, for Emerson, is action. Work, labor, and suffering—these are keys to developing the human powers of language and thought. In his 1844 speech, "New England Reformers," Emerson complained that too often when school is over, "We . . . come out at last with a bag of wind, a memory of words, and do not know a thing. We cannot use our hands, or our legs, or our eyes, or our arms" (Emerson, 1899, pp. 244–245). Real education occurs through experiential learning: "The sight of the planet through a telescope," he continues, "is worth all the courses on astronomy" (Emerson, 1899, p. 245). Action is most educative, for Emerson, when it stems from individual human purposes, both to teach and to learn. When we are interested in learning and teaching, education becomes "natural." This means that student freedom becomes essential for learning to take place: "The secret of Education lies in respecting the pupil. It is not for you to choose what he shall know, what he shall do" (Emerson, 1884, p. 116). Emerson also emphasized the educational worth of experience that comes about through acting in everyday life. He regretted the fact that only the distant and exotic seem to be valued in education: "I ask not for the great, the remote, the romantic. . . . I embrace the common, I explore and sit at the feet of the familiar, the low" (Emerson, 1837/1982a, p. 102).

In his democratic embrace of the educational potential of ordinary life, experiential learning, and child-centered experiences, Emerson foreshadows John Dewey and strands of American progressive education. More recently, his celebration of the educational potential of nature intersects with the environmental education movement. His emphasis on the development of autonomy has been an important influence on liberal educational thought, while his emphasis on the growth of individual power and self-trust was of keen interest to Friedrich Nietzsche. Indeed, Emerson presents a vision of what education would look like if it took individuality seriously, a vision he recognized as antithetical to schooling as it was (and is) practiced: "Our modes of Education aim to expedite, to save labor; to do for masses what cannot be done for masses, what must be done reverently, one by one . . ." (Emerson, 1884, p. 123).

Epistemologies, Teacher and Student

"Personal epistemology" refers to the beliefs that people hold about knowledge and knowing; the psychological study on this topic started with the seminal work of William Perry in 1970. It seemed plausible that the ideas students have about the nature of knowledge and how one comes to know something influence the learning strategies that they

use, while the epistemologies of teachers seemed likely to influence how they teach.

Personal epistemology researchers concentrate on two broad dimensions of epistemology: (1) the nature of knowledge and (2) the nature of knowing. The nature of knowledge is conceptualized in terms of beliefs about its simplicity (simple vs. complex) and about its credibility status (certain vs. tentative). The nature of knowing is conceptualized in terms of the source of knowledge (internal or external to the knower) and the means of justification (authority vs. evidentiary standards). Personal epistemology researchers generally argue that a developmental progression exists across the life span, wherein individuals start from an absolutist stance that sees knowledge as simple, knowable with certainty, as having its source in the world, and justified by trusted authorities; later they move to holding an unmoored multiplism (or relativism) in which knowledge is regarded as uncertain, supposedly authoritative sources are untrustworthy, and all knowledge claims are equally justifiable. Later in development, this multiplism is resolved into an evaluative stance that concedes that knowledge is constructed and is not knowable with absolute certainty, but that nevertheless asserts that knowledge claims can be justified according to standards of reason and evidence.

Research has shown that there is some degree of association between epistemological beliefs and learning strategies, school achievement, and course-taking patterns. There is a tendency for students who have adopted the evaluative stance to have higher achievement, to take more math and science courses, and to use deeper learning strategies. At the same time, however, it must be acknowledged that clear and direct associations between professed epistemic beliefs and students' learning in subjects such as science or math have been hard to come by, and studies have faced a range of problems of measurement and conceptualization.

Research on teacher epistemologies has largely focused on associations between epistemological beliefs and other kinds of beliefs about teaching or learning. Compared with studies of student epistemologies, research on teachers is limited. Within math and science specifically, the general finding is that the teachers across K–12 grade levels tend to have what researchers consider naive views of the epistemology of their subject specialties. As yet, relatively little work has been done to trace the influence of these views on teaching practices. There is some empirical suggestion that myriad concerns and in-the-moment judgments have a much stronger effect on instructional practices than epistemological beliefs.

Research on personal epistemologies has been hampered by a rather large variety of definitions of what counts as "epistemological." Models of epistemological development proliferate, so far with little effort to discriminate among them. Connections between relevant developmental milestones, such as attainment of the ability to engage in causal reasoning, or development of the child's theory of mind, are underexplored. Questions remain concerning how an individual's beliefs about knowledge and knowing are related to the individual's beliefs about learning, and whether the latter should be considered part of a personal epistemology.

A persistent concern in personal epistemology research has been the reliance on general survey instruments that lack validation with other possible assessments of epistemological belief. Research subjects are typically asked to state their level of agreement with general statements about knowledge or about knowing—but such assessments are far removed from people's actual efforts to construct or evaluate knowledge for themselves and presuppose that individual's epistemic beliefs are stable and available for explicit reflection. A related problem is that commonly used instruments often include items about topics that bear little relation to epistemology.

There is another significant issue, namely, that a wide variety of empirical evidence undermines claims that there is a simple developmental trajectory from absolutism to evaluativism. People can espouse apparently contradictory epistemologies at the same time, both within and across subject matter or judgment domains. The assignment of individuals to broad epistemological positions may reflect researchers' biases more than the actual beliefs of the people concerned. This has spawned a variety of theoretical models of epistemological development; these include developmental theories as described here and models that posit multidimensional, somewhat independent belief systems. At the moment, the field appears to be in ferment without a clear way of discriminating between competing models.

A related issue is that the dominant conceptualization of epistemological beliefs as described above seems simplistic both intuitively and philosophically. Intuitively, it is not hard to recognize that some knowledge is simple, such as knowing

your own phone number, but other knowledge is complex, such as knowing the theory of natural selection. The epistemological status of the first is different from that of the second—and this makes it difficult for students to give a single, universally applicable account of the nature of their beliefs. Philosophically, epistemologists concern themselves with a much broader range of issues than is typical in personal epistemology research, and in particular emphasize the aims of knowing, and the role played by values in epistemological matters.

Models of epistemological development thus are making efforts to be more philosophically rigorous, and investigative methods are changing to enable comparisons between what researchers now distinguish as professed epistemologies (what people say that they believe about knowledge and knowing) and enacted epistemologies (what people do when they construct and evaluate knowledge themselves). This includes a shift away from assessments of beliefs toward the study of processes of epistemic cognition. This shift stems in part from research on learning in the disciplines, especially math and science. In science, for example, the evidence is quite clear that students' efforts to investigate scientific questions (enacted epistemologies) share much with professional scientific practice, while their professed epistemological beliefs about science seem hopelessly naive and immune to instruction. It remains an open question how the intuitive and apparently tacit ideas students apply to their own knowledge construction can be developed into explicit conceptions of the epistemologies of particular disciplines of science, mathematics, and others.

Epistemology, Multicultural

In educational practice and research, the term *epistemology* has come to refer to a wide range of questions and theories about knowledge that have traditionally come under the purview of philosophy of knowledge, and more broadly under sociology and anthropology of knowledge, and psychology. These questions include what knowledge is, who can claim to have it, the differences (if any) between knowledge and belief (or between knowing and believing), what count as sources of knowledge, and how knowledge is acquired or developed. The term *multicultural epistemology*, which is not used very frequently, is open to multiple interpretations that depend on the underlying conceptions of both "epistemology" and "multiculturalism" that are held. This entry begins by addressing the difference between multicultural societies as phenomenon and multiculturalism as policy or attitude. It then addresses three possible interpretations of "epistemology," and how they have manifested themselves in uses of the term *multicultural epistemology*. For each of these interpretations, it discusses the bearing that "multicultural epistemology" has on education.

Multiculturalism and Cultural Diversity

The adjective "multicultural" is ambiguous because it can refer to multicultural*ity*, that is, the neutral fact that most contemporary societies are made up of numerous cultural groups, as well as to multicultural*ism*, that is, the positive view that the different cultures in a given society ought to be respected, accommodated, or celebrated. Multiculturalism can be a view held by an individual or a group of people and can become enshrined in official government policy. "Multicultural epistemologies" in the plural can descriptively (i.e., sociologically, anthropologically) refer to the different ideas about knowledge that can be found in the different cultural groups in a society. "Multicultural epistemology" in the singular tends to refer to the pursuit of epistemological

issues within the traditional field of philosophy of knowledge—but a pursuit that actively seeks to be inclusive and respectful of the different cultural groups in a society and is, therefore, multiculturalist in its orientation.

Three Interpretations of Multicultural Epistemology

Epistemology With a Multiculturalist Sensibility

If epistemology is seen as a philosophical practice, as the part of the larger discipline of philosophy that occupies itself with the study of knowledge and how claims to know something are warranted or supported, then "multicultural epistemology" may refer to this epistemology done with a "multicultural sensibility." This is the interpretation that D. C. Phillips and Jon Levisohn advocate, and in doing so, they borrow the idea of doing philosophy with a particular sensibility from the feminist epistemologist Helen Longino. Longino had distinguished between doing "feminist epistemology" and doing epistemology with a "feminist sensibility." The former would refer to a distinctively feminist philosophical practice, using its own feminist criteria for what constitutes good epistemology, while the latter would refer to the common philosophical practice of epistemology carried out with a feminist awareness of how the traditional understandings of knowledge, knowing, and knowers have excluded women. Similarly, then, doing epistemology with a multicultural sensibility would mean the common philosophical practice of epistemology carried out with a multiculturalist awareness of how the traditional understandings of knowledge, knowing, and knowers have excluded those from non-European backgrounds.

Multicultural epistemology, in this interpretation, could, for example, ask critical questions about the importance of "knowledge by acquaintance," the type of knowledge captured in statements like "I know you" or "they know the river." Such statements are different from and broader than ones such as "I know that you prefer your coffee with milk" or "they know that the river is twenty feet deep," which express "propositional knowledge." Knowledge by acquaintance is a more intimate, encompassing knowledge that is gathered over time, sometimes shared in a community rather than held in an individual mind, and not necessarily written down. Although some philosophers have been dismissive of knowledge by acquaintance as a distinct type of knowledge, it can be highly valued in a community. For example, educational researchers can measure Chinese immigrant children's competency in English as well as in Mandarin, and they can assess how losing their ability to speak Mandarin affects the children's learning of English. Such research findings are typically captured in propositional knowledge. However, the lived experience of maintaining or losing the language that one's grandparents speak is not so easily captured in propositional knowledge. A Chinese community might say, then,

> We know how a younger generation's inability to speak Mandarin affects intergenerational ties, we have seen how thinking in English rather than Mandarin has changed their outlook on the world: we *know* language loss. Why are policy makers more interested in the propositional knowledge in tables and graphs than in our community's knowledge of language loss when they write new policy on language education?

Multicultural Epistemologies

Others have used the term *epistemology* not to refer to a philosophical practice but rather to a particular set of beliefs about knowledge that are the outcomes of this practice. In this way, scholars may refer to "an epistemology," to "so-and-so's epistemology," or to "epistemologies" in the plural. If epistemology is taken in this way, then "multicultural epistemologies" could refer to the multiple sets of beliefs about knowledge coexisting in a multicultural society. If the primary multiculturalist principle is that the different cultural groups in a society are entitled to their own values, beliefs, and practices, then "multicultural epistemologies" could refer to the idea that the different cultural groups in a society have, and are entitled to, their own ideas about knowledge.

The difficulty with this idea, in the simple way it has been stated here, is that each cultural group's claims to know can be assessed only by that group's own criteria. Each cultural group's claims to know, and the warranting or justificatory criteria that are used, are thus insulated from outside criticism, a situation known as relativism. So if a group, for example, claimed that, in its culture, it was believed that knowledge resided in microchips implanted in people when they were abducted by aliens, a multiculturalist would have to shrug her or his shoulders and say, that is their knowledge, generated by their epistemology, and I have to respect that. From the

perspective of liberal education this is not very satisfactory, as the ability to assess the reasons people give for their claims is considered an important educational outcome. While other educational perspectives might value inclusiveness, respect for difference, and care for one another over the rational ability to assess the reasons given for claims, most would not want to fully embrace relativism and abandon all criteria for assessing knowledge claims.

There is, then, an important tension between "epistemology with a multicultural sensibility" as described earlier and the "respect for multicultural epistemologies" that has just been discussed: the former is *normative*, which is to say, it offers views on what ought to count as knowledge, and the latter is *descriptive*, which is to say, it observes what beliefs about knowledge exist within the cultural groups in a society but does not allow for a cross-cultural assessment of these beliefs.

Epistemology of Multicultural Education

A third interpretation of "multicultural epistemology" is as the epistemology (in the sense of a set of beliefs about knowledge) that is assumed by those who practice multicultural education. In other words, what do those who practice multicultural education assume knowledge to be, particularly knowledge about a multicultural society itself? This is the interpretation that Nancy Lesko and Leslie Rebecca Bloom use when they argue that, ironically, multicultural education often relies on a positivist epistemology. By this, they mean that education with a culturally diverse group of students and about multicultural society often relies heavily on factual, propositional knowledge about multicultural society rather than on other forms of knowledge that may be brought to the class by the students themselves. Lesko and Bloom write that they have observed many attempts to replace students' false beliefs about multiculturalism and multicultural societies with beliefs that are true (as judged by their correspondence to multicultural society as it can be observed and measured). Such attempts, they believe, disrespect the cultural diversity of the students as they validate only one type of knowledge about multicultural society and force it on students who bring to school their own knowledge of such a society. Lesko and Bloom argue that the students' subjective experience, and knowledge by acquaintance of living in a multicultural society, ought to be taken seriously as a type of knowledge and that a dialogical approach to knowledge co-construction is more appropriate than a focus on accurate knowledge about multicultural society based on objective evidence.

If knowledge co-construction in a multicultural classroom proceeds without any shared criteria for what counts as knowledge, it falls prey to the relativism mentioned above. However, this does not diminish the important question of what epistemology, in the sense of philosophical practice or in the sense of set of beliefs about knowledge, is best suited to support multicultural education. How might we best go about teaching students about various theories of knowledge if at the same time we wish to promote respect for cultural difference? How can we teach students to assess the warrants for knowledge claims, but also to be mindful of the contexts in which they do so, and the voices that are or are not heard as legitimate makers of knowledge claims? There is no one-size-fits-all approach with which we can assess the warrants for statements made by, for example, candidates in a presidential election campaign as well as those made by Indigenous people in land claims.

Epistemology as Ill-Fitting Box?

One of the difficulties not addressed by the label "multicultural epistemology" is that it continues the use of the term *epistemology*. While the introduction of the word "epistemology" into English is relatively recent, dating back no further than the middle of the 19th century, discussions we would now call "epistemological" go back much further in Western and Middle-Eastern philosophy. The tendency to seek precision through analysis and taxonomy has led to distinct names for disciplines and subdisciplines and fields and subfields, including, for example, "epistemology," "ontology," and "ethics" in philosophy. While such distinct subdisciplines and fields allow for sought-after specialization and precision, they can also treat phenomena and concepts that are inseparable in their real-life manifestations as being distinct or separable. The philosophical practice of epistemology can be perceived as an ill-fitting box by those from cultural backgrounds in which analysis and taxonomy are less valued. Epistemology has traditionally presupposed that the study of knowledge can be conducted separately from, for example, ethics or sociology, but the question of what counts as a warrant for knowledge, who is considered a legitimate knower, and how to balance a skepticism

for what people say with a respect for persons are not so easily separable in everyday life. More recently, scholars in social epistemology have sought to remedy these artificial separations by reconnecting epistemology with ethics or sociology of knowledge. Miranda Fricker, for example, has examined how some people suffer the particular injustice of being denied a capacity as knower because they are not recognized as credible based on the racial, gender, or other group to which they belong. And Helen Longino has argued that when some voices are systematically excluded from scholarly debate, the knowledge resulting from that debate suffers as it has not passed and been refined by the most comprehensive critical scrutiny.

Equality of Educational Opportunity

The concept of equal educational opportunity was thrust into prominence in the United States in the Supreme Court's 1954 decision in *Brown v. Board of Education*. The Court reasoned that equalizing educational opportunity had become imperative because it had become so tightly entangled with equalizing opportunity to access society's goods more generally. The focus of the Court's decision was ending the legalized segregation of Black children in public schools. In 1965, with the passage of the Elementary and Secondary Education Act, the imperative to equalize educational opportunity was extended to low-income children. In subsequent years, court decisions and legislation extended the imperative further to address disability, language, and gender. Today, there are calls to include sexual orientation and immigrant status, among other categories.

Since *Brown*, considerable agreement has been reached that providing equal educational opportunity is morally required, at least for racial groups, low-income children, and girls and boys. However, just what this requirement entails more specifically continues to be controversial.

Inputs Versus Results

In his celebrated 1966 study of educational inequality, the sociologist James Coleman stimulated interest in the philosophical question of the meaning of the principle of equal educational opportunity, particularly regarding whether it should be understood in terms of school inputs—for example, the facilities and curriculum materials supplied to children—or in terms of the results schools produced, for example, children's academic achievement. Coleman suggested that a defensible conception of equal educational opportunity must involve the equalization of educational results. For, in making the determination of whether children were being afforded equal educational opportunities, equality of inputs alone is insufficient. Indeed, to identify something as a genuine educational input, it must be related somehow to the production of educational results.

At the time, philosophers were by and large dismissive of the idea that equal educational opportunity can or should be defined in terms of educational results. They countered with the observation that the existence of an educational opportunity provides a chance but no guarantee of producing educational results. Opportunities must be exercised to produce results, and one may choose to forego exercising them.

This choice-based conception of equal educational opportunity is problematic in several ways. First, Coleman is not unique in adopting a results-based position. In the 1974 *Lau v. Nichols* case, the U.S. Supreme Court rejected the San Francisco Unified School District's argument that it was providing

monolingual Chinese-speaking children with equal educational opportunity by providing them with the same inputs (books, teachers, and desks) that were provided to English-speaking children. The Court declared that such opportunities are not meaningful because there is no reason to believe that they can produce the desired educational results. This echoes Coleman's analysis. The same general contours are found in John Dewey's claim that the educative value of a given experience depends on how well it interacts with the characteristics of given individuals at the point in time it is presented to them. The general point is that educational opportunities cannot be abstracted from the interactions between the characteristics of individual children and what the institution of schooling provides to them. As the *Lau* case dramatically illustrates, what constitutes an educational opportunity for one individual can be quite meaningless for another.

A second way in which the choice-based conception is problematic is that educational results must be produced to open future educational opportunities. Literacy and numeracy are obvious examples of educational results that must be produced to provide children with meaningful educational opportunities as their educational careers unfold. The problem here is that the choice-based conception is blind to the special character of children's opportunities. The idea of having, but failing to exercise, an opportunity can be readily applied in certain circumstances involving adults, for example, as in "Arturo had the opportunity to attend Harvard but declined it." But children's educational choices cannot be approached in the same way, as in "Six-year-old Susan had the opportunity to learn to read but declined it." Susan would not be afforded such a choice—she would not be capable of responsibly exercising it.

The concept of equal educational opportunity must be viewed in terms of educational careers that include the achievement of numerous educational results, many or most of which are not chosen. The relationship between educational opportunity and educational results may be expressed as follows: *inequality of educational results provides prima facie but defeasible evidence of inequality of educational opportunity.* In the case of African Americans, for example, the cumulative evidence of their relatively lower achievement strongly warrants the conclusion that they are denied equal educational opportunity. Closer investigation reveals that the schools that they attend are relatively inferior. The original claim that African Americans are, as a group, denied equal educational opportunity is not defeated. By contrast, one might claim that Arturo was denied equal educational opportunity compared with students with Harvard "legacies" because he attended State University rather than Harvard. Suppose on further investigation, however, it was determined that Arturo could have gone to Harvard but chose not to do so. He thus was not denied equal educational opportunity, and the original claim is defeated.

General Conceptions of Equal Educational Opportunity

Few, if any, advocate strict equality among education results. Analysis instead turns on the questions of how much educational inequality is permissible and due to what causes. Different answers to these questions are provided by three general conceptions: formal, horizontal, and vertical.

Formal Equal Opportunity

Formal equal educational opportunity requires that individuals not be denied admission to an educational institution because of discrimination on the basis of race, gender, disability, and so on. Formal equal educational opportunity is certainly an advance over the alternative of naked discrimination. However, it is a very weak conception of equal educational opportunity. On this conception, a child is not denied equal educational opportunity if she is turned away from a school because her parents cannot afford to own a home in an adequately funded school district, and if she must therefore attend an inferior, underfunded school. And this child would not be seen as being denied equal educational opportunity if she later failed to qualify for college because of her previous inferior education.

Horizontal Equal Opportunity

Horizontal equal educational opportunity requires equalizing educational inputs across educational institutions. The child of the previous example would be denied equal educational opportunity under this conception because her underfunded, inferior school does not provide her the resources needed to succeed equally to the children of the wealthier district. Although an advance over formal equal educational opportunity, the horizontal conception is also too weak. As illustrated by the *Lau* decision, educational inputs cannot be identified as such when abstracted from the individuals to whom they are provided. If the child in the example

is hard of hearing, for example, then being provided with the same inputs as other children, even in an adequately funded district, will not ensure that she is being provided with equal educational opportunity. Again, attention must be paid to the particular characteristics and associated needs of individuals to provide a meaningful kind of equal educational opportunity. This leads to the vertical conception.

Vertical Equal Opportunity

Vertical equal educational opportunity requires equalizing educational inputs from the bottom to the top of the learner advantages/disadvantages spectrum in given education contexts. Using the illustration of the *Lau* decision once again, the educational opportunities of Chinese-speaking children are equalized by tailoring educational inputs to their make-up, in this case providing some proven form of bilingual instruction. The same logic applies to income, race, gender, and disability. In each case, children may need to be provided *different* educational inputs in order to enjoy *equal* educational opportunity.

The Equality and Adequacy Frameworks

The two leading contemporary philosophic approaches to the analysis of equal educational opportunity are the equality and adequacy frameworks. Both are vertical conceptions.

The Equality Framework

The equality framework is associated with a meritocratic conception of equal educational opportunity. It permits educational inequality to the extent that it results from talent and motivation but not from sources such as social and economic class. The amount of permissible inequality is thus a function of inequality in talent and motivation. A more radical version does not permit even talent or motivation to be legitimate sources of inequality, to the extent that these are systematically related to social and economic class.

The equality framework conceives equal educational opportunity in terms of material equality. It emphasizes that education is a *positional good*, the value of which is determined relative to how much others possess of it, and by the fact that it enables the acquisition of other goods such as employment, a good income, and health care. For society to be just, then, education must be justly distributed, which is what the meritocratic conception of equal educational opportunity is designed to ensure. It does so by distinguishing morally relevant sources of educational inequality, such as talent and motivation, from morally irrelevant sources, such as the social economic class into which one is arbitrarily born. Permitting morally irrelevant sources to determine how much education individuals attain is unjust on this view, for people should not benefit or be disadvantaged by what they cannot be credited or blamed for, which surely includes the social economic class into which they are born.

The Adequacy Framework

The adequacy framework conceives equal educational opportunity in terms of political equality. Although not unconcerned with material equality, the adequacy framework places much greater emphasis on democracy than does the equality framework. This difference applies both to the question of what is to be equalized in the name of equal educational opportunity and the level of equality that is required.

Different groups of people place different value on education. The adequacy framework acknowledges this and holds, further, that a certain amount and kind of resulting educational inequality should be permitted in a democratic society. Equal educational opportunity is thus not a constant function of other variables as in the way the equality framework relates permissible inequality to talent and motivation. Rather, the adequacy framework specifies a certain threshold of education below which no educable child should be allowed to fall. This threshold limits the discretionary space open to democratic bodies, while permitting them to create inequality above the threshold.

Key to the adequacy framework is how it closely ties education to democracy. This is in contrast to the equality framework that treats education on the model of other goods to be distributed, emphasizing its position relative to other goods. In particular, the threshold is defined in terms of the level and kind of education required to foster the kind of equal status as a citizen associated with the ability to effectively engage in democratic deliberation. This is the conception of equal educational opportunity that a democratic society can legitimately insist its educational system provide in the name of democracy itself. Achieving it will spill over into requiring the achievement of a threshold of material well-being, without which equal citizenship cannot be realized.

Equality Versus Adequacy: The Disagreements

The equality and adequacy frameworks are not simply alternative approaches to equal educational opportunity. Their advocates are competitors, each critical of the other's stance both on how to avoid leveling down as the means to achieve equality, such that educational opportunity is equalized but at an inadequate level, and how to recognize education's position relative to other goods so as to avoid injustice overall.

The Leveling-Down Issue

The leveling-down issue is associated with the equality framework. Because the framework does not incorporate any substantive standard of education, one way to achieve equality is simply to reduce what is provided to those at the top of education resource distribution in order to reduce their advantage. Avoiding this maneuver has actually been a concern regarding the response of school districts to court decisions requiring the equalization of funding.

The equality framework may, indeed, face a practical political problem with regard to the leveling down of resources so as to achieve educational equality. But this is not the fault of the equality framework, philosophically speaking. The equality framework is "prioritarian," meaning it gives priority to improving the position of the disadvantaged in policymaking. It is by no means clear that leveling down is always, or usually, the best way to do this. Furthermore, the equality framework recognizes that education has nonpositional, or intrinsic, value, in addition to positional value. Coming to appreciate a good literature or an elegant mathematical proof are examples. The idea of leveling down does not apply to this kind of educational good because one individual's possession of a certain degree of it does not affect another's.

The Positional Good Issue

The adequacy framework avoids the leveling-down problem by requiring a substantive educational threshold. Advocates of the equality framework do not find this a compelling reason for adopting the adequacy framework. Indeed, because it pays too little attention to the positional aspects of education as a good, on their view, the adequacy framework is charged with being indifferent to inequality above the educational threshold that can result in unacceptable levels of inequality in other domains. Furthermore, the adequacy framework faces its own practical political problem, in this case, that the threshold might be set too low. Indeed, wealthier parents would have an incentive to support just that and then devote extra resources to their children's educations above the threshold. What makes matters worse than in the case of the equality framework is that the state would be approving of inequality in adopting an adequacy framework.

Like advocates of the equality framework, advocates of the adequacy framework do not take the practical political problem to be a decisive criticism of their view, philosophically speaking. Their rejoinder to advocates of the equality framework regarding the positional good issue is that in a democracy, education is not, or should not be, a largely zero-sum good. Instead, it should be grounded in equal citizenship, which requires that certain relationships exist among citizens that enable them all to effectively participate in social and political life. This requires fostering tolerance, mutual respect, cooperation, and other skills that are acquired and honed collectively and that are thus quite unlike positional goods. Moreover, citizens who possess these democratic characteristics will not be disposed to use educational inequalities to unfairly gain other benefits.

Conclusion

A general, not to say unanimous, point of agreement has emerged among philosophers regarding equal educational opportunity: Formal and horizontal conceptions are too weak; a vertical conception is required. But controversy surrounding the concept of equal educational opportunity is by no means settled. The disagreement about whether the criterion of a vertical conception should be equality or adequacy remains intense. Resolving this disagreement may well turn on which of the equality versus adequacy frameworks, if either, takes hold in the practical political domain.

Erasmus

Desiderius Erasmus (1469?–1536) was born in Rotterdam, the illegitimate son of a physician's daughter and a priest. From these inauspicious beginnings, he rose to become Europe's premier Latinist, as well as a celebrated biblical scholar and proponent of educational and religious reform. While as a young man, he was absorbed in the Greco-Roman classics; in his middle years, he turned his attention primarily to biblical scholarship. For the last 15 years of his life, he was embroiled in the controversies surrounding Luther's challenge to the Roman church.

During Erasmus's lifetime, there were two major systems of learning, which simultaneously competed with and supplemented each other. Scholasticism, dominant in the universities, had flowered in the 13th century, with the reintroduction of the logical works of Aristotle into circulation in Western Europe. Scholars were fascinated by the tools Aristotle's philosophy provided for unlocking the mysteries of Christian theology. Humanism, a product of the Italian Renaissance, abjured speculative theology and philosophy in favor of the *studia humanitatis*: studies of human beings, focused on living well in the world. Ethics, political philosophy, and life in the family and community were central to this program, which was rooted in the Greco-Roman classics. While the scholastics particularly favored dialectic (logic), humanists embraced rhetoric (the art of persuasion).

Erasmus's background exposed him to both of these forces. Early in his life, he gained a foundation in Latin letters at a school associated with the Brethren of the Common Life in Deventer, a movement of pious laymen who espoused a life of simple, humble piety. As a youth, he entered the Augustinian monastery at Steyn, where he took advantage of the extensive library to gain knowledge of the classics. In 1492, he enrolled at the University of Paris to study theology through the patronage of a bishop. Here, in the heart of the world of scholasticism, Erasmus found himself far more attracted to the society of humanists than to his theological studies. He supported himself through private teaching and published the first editions of pedagogical works for which he became famous: the *Adagia*, a collection of adages or commonplaces (with explanatory notes describing their meaning and origins in classical literature), and the *Colloquies*, a set of Latin dialogues on contemporary subjects, modeled on the Socratic dialogues. He would expand both collections through numerous editions over the remainder of his life. Other important works include the *De Copia* (1512), a manual for writing in the "abundant style" based on a section of Quintilian's *Institutiones Oratoria*. One of his students brought Erasmus to England in late 1498, where he met lifelong friends John Colet (who in 1509 became the founder of St. Paul's School) and Thomas More. Erasmus was inspired by these companions to turn his focus from the pagan classics to the literature of Scripture. His most famous work, *Praise of Folly* (1511), was dedicated to More.

Erasmus embarked on the study of Greek and began a thorough scholarly examination of the New Testament, including a new Latin translation that departed from the Vulgate (which had been universally in use up until that time), a critical edition in the original language, and an elaborate set of annotations. He expanded on the philological tools developed and utilized by the humanist Lorenzo Valla (1407–1457), who was highly attuned to language as an ever-evolving product of history. By accumulating and comparing manuscripts, Erasmus sought to arrive at an authoritative reading based on his knowledge of linguistic practices during the period in which the text was written. This work would involve him in numerous controversies, particularly with those embracing a scholastic approach, forcing

him to defend his translation in numerous apologetic works and in three subsequent editions of his New Testament. He also composed a set of paraphrases on the books of the New Testament and produced critical editions of the complete works of many of the Latin and Greek Fathers of the Church.

As a religious reformer, Erasmus promoted the idea of the *philosophia Christi* (philosophy of Christ), which he defined as an inner transformation brought about by encountering Christ in Scripture, in contrast to the highly technical philosophical approach of the scholastics. A critic of relics, private masses, pilgrimages, and special vows, Erasmus advocated a simple faith and humble conformity to the will of God. His approach retained its humanist emphasis on formation of the character through encounters with the finest texts; to Erasmus, reading Scripture was the ultimate act of communication for which one prepared through acquaintance with the figurative language of the best classical writers. With the advent of the Lutheran reform, Erasmus was unwillingly swept into religious controversy. For several years, he remained detached from the growing division, but finally, in 1524, he proclaimed his allegiance to the Roman church with his *Discussion on the Freedom of the Will.*

Erasmus's educational program was closely linked to his religious reform. Throughout his life, he advocated an approach that valued the moral formation of students through encounters with the best literature. He believed that the process of mastering Latin should be made as enjoyable as possible to make young people associate learning with pleasure. He subscribed to the humanist view that the ability to speak and write well was the foundation for a well-lived life and that by turning one's mind to the highest ideals expressed in the most beautiful Latin, the student could best realize his potential. His *Adagia* in particular provided young scholars with access to a wealth of knowledge in a form designed to stimulate their interest in developing a deeper understanding.

Essentialism, Perennialism, and the "Isms" Approach

Essentialism and *perennialism* are terms coined in the mid-20th century to identify separate but related approaches to educational theory and practice. These terms have retained minor currency in an approach to teaching philosophy of education known as the "isms" approach. Even more than the isms approach in general, essentialism and perennialism are largely absent from contemporary philosophy of education or curriculum theory, though they persist in some college and university courses and are well represented on the Internet. These two isms are examples of historical efforts to make sense of educational tensions that became particularly salient in the early 1900s but that remain unresolved a century later. While today's educational theorists and reformers do not typically use the terms *essentialism* or *perennialism*, they continue to debate tensions between traditional educational aims for all children versus contemporary educational aims for students based on different student backgrounds, aspirations, and social conditions. *Essentialism* and *perennialism* were terms originally intended to characterize the most traditional of educational outlooks.

Isms in General and in Educational Theory

What has been called the isms approach in philosophy of education is simply an application of a common linguistic convention to academic purposes. We use the suffix *ism* most frequently to categorize commonalities in thinking and to distinguish them from one another, whether these be religions (Buddhism, Judaism, and fundamentalism), formal philosophical systems (pragmatism and existentialism), political ideologies (liberalism and socialism), convictions and biases (vegetarianism and racism), views of human learning (behaviorism and constructivism), patterns of thought and speech (dualisms and malapropisms), arts genres (impressionism and surrealism),

and so on without end. The conventionally regarded longest word in the English language is an ism (antidisestablishmentarianism). The ism suffix typically identifies ways of thinking or believing and enables us to classify these ways of thinking conveniently.

To one extent or another, then, all isms are historical constructions: efforts to make sense of a complex thought world by creating classifications and categories under which multiple conceptual phenomena can be ordered, whether the phenomena in a given category are words, treatises, or deeds. Racism has countless manifestations, as do socialism and impressionism. The phenomena that these three particular terms describe existed long before the terms were introduced in the 19th and early 20th centuries, but these terms have become familiar elements in our cultural vocabulary. What has been called the "isms approach" is first and foremost an approach to culture, language, and thought, not just an approach to teaching educational theory.

In educational theory, the isms approach had a kind of heyday in the early and mid-20th century, again as a response to conditions that preceded it. Theodore Brameld, an academic philosopher and professor at New York University, introduced a taxonomy of isms in 1950 that featured "four major outlooks," as he would term them toward the end of his career: perennialism, essentialism, progressivism, and reconstructionism. That these were Brameld's unique construction of what he considered to be "principal patterns" of thought, as he termed them, is evident from the fact that he chose not to use a variety of other isms with which he was familiar and which others have used before and since. Among these are idealism, realism, Thomism, and existentialism, which remain prominent among some textbook and web-based presentations of isms today, while perennialism and essentialism have receded.

Brameld noted in 1974 that his preferred isms had never been taken seriously by academic philosophers, nor were his own isms largely taken up by colleagues writing in the field of philosophy of education. He certainly could not have foreseen that 40 years later these four categories would still be alive and well on the web and that the isms approach in general would still be used in training teachers and philosophers of education. In 1986, one of the most comprehensive books ever written on curriculum theory listed seven different philosophical schools of thought: idealism, realism, neo-Thomism, naturalism, pragmatism, phenomenology, existentialism—with no mention of essentialism or perennialism. Almost 30 years later, the vocabulary of educational theory has changed, but the use of isms remains in theoretical markers, such as feminism, postmodernism, poststructuralism, postcolonialism, and others.

Such isms are distinct from those that Brameld offered in that they represent intellectual and artistic commitments entirely independent of educational theory, while Brameld intended his four categories to represent different approaches to theorizing about education specifically. There will always be a replenishing supply of isms; whether educational philosophers see them as useful in their theorizing and/or in their teaching is another matter.

The distinction between the use of isms in educational theorizing and in college and university pedagogy is an important one. Brameld was trying to make conceptual distinctions in educational theory and practice by using these four categories to speak to theorists and practitioners. Philosophers of education today do not use these older isms in their professional discourse, even disavowing them—but these older isms are still used by some college faculty to help novice educators in colleges and universities understand how educational practices and preferences are tied to deeper systems of philosophical thought—from idealism to existentialism to pragmatism to postmodernism. A popular text in philosophical foundations of education, published continuously for the past 18 years, devotes chapters to these isms as well as to Marxism, behaviorism, and reconstructionism, with extensive attributions to Brameld but nothing, however, on essentialism or perennialism.

Essentialism and Perennialism: Illustrative Isms From the Mid-20th Century

Brameld's apparent purpose in constructing his four particular categories was to show, in sharp relief, how conflicting ways of thinking about education had dominated the discourse in the first half of the 20th century. He was not trying to be comprehensive with respect to possible philosophical points of view about education: He was contrasting two traditional or conservative perspectives with two less traditional or progressive perspectives in educational theory and practice—in particular to argue for the superior value of the reconstructionist perspective, which he saw as the most promising path to democratic social change. His four categories were offered in response to now familiar late-19th- and early-20th-century debates about the purposes of education in

a changing society—one that was becoming rapidly more diverse demographically while urbanizing and industrializing at a disruptive pace. Dewey and others of similar mind argued that the old traditions in education could no longer suffice, while critics responded that the old traditions were needed now more than ever. Brameld characterized two variants of the more traditional position as essentialism and perennialism, and two variants on the less traditional position as progressivism and reconstructionism.

That these categories are taught today, with lessons and lectures posted on the Internet—often without attribution to any particular mid-20th century philosopher—creates a kind of reifying effect. It is as if these categories are objective, settled, and enduring knowledge in the field, and not acts of subjective interpretation that were offered in a particular context. It is something of an irony to notice that these terms have become inert knowledge, as the philosopher John Dewey might have characterized them, and objective categories to be learned as part of the tradition of the field. Such traditional knowledge was part of what Brameld was criticizing by making distinctions between essentialism and perennialism, on the conservative, more inert side, and progressivism and reconstructionism, on the more dynamic, socially responsive side.

As taught today, when they are taught, the meanings of essentialism and perennialism seem not to have strayed significantly from Brameld's original intentions. Though he viewed both positions as fundamentally conservative, Brameld saw perennialism as a classicist view that centered on the *perennial* value of the teachings and texts of classical Greece and medieval Europe—such as what Jefferson expected when he recommended Latin grammar schools for deserving youth in the state of Virginia. In contrast, essentialism was more changeable as great texts evolved over time and could be used to teach the great truths of human existence through a common core of *essential* cultural knowledge. Both were clearly teacher centered and curriculum centered, instead of child interest centered or social context centered, and both emphasized the development of traditional intellectual capacities and skills in mathematics, literacy, and reasoning.

Few educational theorists today would take something akin to a perennialist stance for all children and youth in schools; there is no public call for classics-based education for all, although college students and graduate students can still concentrate on the classics if they so choose. The essentialist view, however, is clearly alive in the use of the "great books" curricula in colleges and universities and in the Common Core State Standards movement in PreK–12 education. The Common Core Standards movement, at the time of this writing adopted by all but a few states in the United States, asserts that there is a body of knowledge, skills, and character traits that we rightfully expect all of our students to develop and that we should hold states accountable for providing this common learning. The argument is fundamentally grounded in democratic values of equity; but Brameld, like Dewey and contemporary critics of the common core, had serious questions about whether such a teacher- and curriculum-centered approach could serve most children well. These questions include the following: Does such an apparently equity-based philosophy make for good educational policy, or will a one-size-fits-all essentialist curriculum serve some children far better than others, depending on the social capital they bring to the school? Does essentialist common core thinking take sufficient account of the differences among children to ensure academic success for all of them, or will it favor some over others? These are the questions that, in part, motivated Brameld's concerns about essentialism and perennialism alike.

A related contemporary debate surrounds the "college for all" discourse in educational policy and practice in the United States. As the 20th century dawned, fewer than 10% of high school–age students graduated from secondary school, while a century later, it climbed to 67%, and at the time of this writing, it is a matter of national concern that only 75% of high school students graduate—the highest rate in decades, but leaving one million seniors who did not graduate high school. The concern among some theorists is that most jobs obtainable in postindustrial society by those without postsecondary education or training do not pay a living wage, in contrast to a time when high school dropouts could obtain more lucrative employment in business and industry—and send their children to college. While "college for all" seems like an appropriate aspiration for a society committed to equitable access to higher education and economic mobility, theorists today are asking, in effect, whether this is an essentialist perspective that again ignores the backgrounds and interests of literally millions of students who, on any evidence-based analysis, are unlikely to attend, much less graduate from, college. They are

asking what secondary education and postsecondary training and education should look like for these students.

In contrast to an essentialist curriculum of Common Core Standards and great books, critics are seeking ways to promote non-college-bound students' intellectual and emotional development and to prepare them to lead fulfilling lives after high school. They are seeking promising educational and economic alternatives for students who do not go to college. But such theorists find it difficult to even *talk* about alternatives to "college for all" without appearing to track students into second-class status in contemporary culture on the basis of their family incomes and ethnicity, an outcome familiar to mid-20th century educational theorists. The Common Core Standards and college-for-all positions are offered by their proponents out of consideration for democracy, equity, and high aspirations for all, but paradoxically, they are grounded also in essentialist theorizing that Brameld considered antidemocratic. This tension, highlighted by antiquated isms, remains unresolved today.

In 2013, poet and cultural critic Alice Walker published a short poem titled "Every Revolution Needs Fresh Poems." At some level, the isms approach of mid-20th century philosophy of education represented the poems of that time, but the poems certainly did not achieve the revolution (or even the reconstruction) that so many educational theorists intended. It is likely that fresh poems are needed.

Ethics in Research

Ethics in research covers three interrelated topics: (1) identifying and defining ethical principles and analyzing ethical issues entailed in the responsible conduct of research; (2) cultivating ethical behavior, including the capacity for ethical reasoning, to address dilemmas that arise in working with people in social, behavioral, and educational research; and (3) regulating ethical conduct.

Research here is defined—in accordance with the Common Rule of the U.S. Department of Health and Human Services, a U.S. federal policy regarding human subjects protection that applies to 17 federal agencies and offices—as any form of systematic investigation involving human subjects. This includes studies conducted via surveys, questionnaires, interviews, focus groups, case studies, experiments, observational techniques, and ethnographies, as well as research development, testing and evaluation, designed to develop or contribute to generalizable knowledge. (Ethics in research is also concerned with research that involves animals. Often, this is referred to in terms of *compliance*—with, e.g., the U.S. Public Health Service Policy on Humane Care and Use of Laboratory Animals—rather than *ethics*, yet the ethical treatment of animals in research is a subject in its own right.)

Ethical Principles and Issues

In discussions of ethics in research, attention is often focused on principles and issues that relate to working with human subjects or respondents in research. As discussed in the 1979 Belmont Report prepared by the National Commission for the

Protection of Human Subjects of Biomedical and Behavioral Research, these include

- respect for persons and their right to make decisions for and about themselves without pressure from the researcher;
- beneficence (and nonmalfeasance, i.e., do no harm) or the obligation to maximize the benefits and to reduce risks to participants in a research or evaluation study; and
- justice or the obligation to distribute benefits and risks equally without prejudice to particular individuals or groups, such as individuals with disabilities or members of a particular race or gender.

It is on the basis of these principles that the familiar notions of voluntary participation in research, informed consent, and assurances of confidentiality are discussed as central ethical issues in research practices involving human subjects.

However, ethics in research also involves ethical principles, such as honesty, integrity, transparency, accuracy, objectivity, impartiality, and trust, especially as these apply to aspects of the research enterprise other than working with people as the subjects or respondents in a study. Ethical considerations arise in all aspects of the research undertaking, encompassing what is commonly referred to as the responsible conduct of research. Conscientious, dutiful, and ethical behavior in research includes matters relating to advising and mentoring, authorship and the allocation of credit, peer review, conflict of interest, intellectual property rights, data management (includes processes for collecting data as well as issues in data ownership and the sharing of data), and research misconduct defined uniformly across U.S. federal agencies as fabrication, falsification, or plagiarism in proposing, conducting, or reviewing research and in reporting research.

Ethics in research also encompasses issues in the field of international research ethics, including the obligations of wealthy nations to ensure that the research they conduct in low- to middle-income countries is relevant to local populations and to take into account the impact of cultural differences on the interpretation and implementation of ethical principles and oversight.

Ethical Behavior and Reasoning

In the preparation of researchers, education and training in research ethics extend beyond reading the customary chapter on research ethics in the standard research methodology textbook. In the United States, every university and organization that receives federal funds for its research provides some form of required training, often using a subscription service to access online instructional modules, such as that provided by the nonprofit Collaborative Institutional Training Initiative. In addition, universities provide courses in research ethics in their curriculum and also offer special workshops and seminars.

In a widely cited formulation, the moral psychologist James Rest argued that ethical behavior is the outcome of four processes:

1. Moral sensitivity (the capacity to recognize the ethical issue at hand)
2. Moral judgment (competence in deliberating alternative courses of action and reasoning about what ought to be done)
3. Moral motivation (personal commitment to action and acceptance of responsibility for the outcome of one's action)
4. Moral character (persistence in the face of the temptation to take the easy way out)

Education in research ethics addresses these processes, particularly focusing on the skills of empathy and perspective necessary to cultivating moral sensitivity as well as the capacities needed to engage effectively in moral reasoning (e.g., grasping the features of the social context of the problem, gathering relevant facts, recognizing who has a stake in the outcome, analyzing and evaluating possible actions, and reflecting on one's action). Case-study methods, checklists, key question lists, and steps in critical thinking are four of the more common decision-making formats or guidelines used in the teaching of ethical reasoning. Research ethics education can also include instruction in ethical theories, including virtue ethics or the ethics of character or (what sort of people should we be) as explained in Aristotelian theory or the ethics of conduct (what sort of actions should we perform) as explained in consequentialist theories (e.g., utilitarianism) or deontological theories (e.g., Kantianism).

Ethical Regulation

Ethical conduct is regulated in four ways. First is self-monitoring on the part of the researcher. Assuming that individuals have developed the kind of moral motivation and character that Rest identified, they would be likely to reflect regularly on the

wisdom of their actions and modify their behavior as demanded in new circumstances. Second, monitoring takes place via codes of conduct as found in professional societies, for example, the American Psychological Association's *Ethical Principles of Psychologists and Code of Conduct*, the American Educational Research Association's *Code of Ethics*, and the American Evaluation Association's *Guiding Principles for Evaluators*. These codes set norms for what members of the profession expect and are intended to foster accountability and responsibility. Of course, these are guidelines for what is expected in professional behavior, although in some cases, there is a suggestion that they will be backed up by sanctions.

Third and fourth means of regulating ethical behavior are governmental regulations and institutional policies, both closely related. There are many federal rules, regulations, and guidelines having to do with ethical conduct in research, including the U.S. Public Health Service Policies on Research Misconduct, the Department of Health and Human Services Regulations, the Federal Whistleblower Protection Act, the Privacy Act as amended, and policies of individual departments—Agriculture, Justice, Interior, Commerce, Education, Energy, Transportation, and Labor. In addition, agencies such as the National Science Foundation, the National Endowment for the Humanities, and the National Institutes of Health each have their own policies and procedures regarding the responsible conduct of research. The National Science Foundation and National Institutes of Health require that all undergraduate and graduate students, postdoctoral researchers, and professors doing research (or supported on fellowships) funded by either agency must have training in the protection of human subjects in research. Each institution is responsible for the content and the delivery of training and its frequency.

The Common Rule requires that every institution or organization doing federally funded research must have an independent ethics committee or ethical review board that reviews all research involving human subjects. This Common Rule also specifies the composition of such a committee. (Each federal agency that funds research may have additional requirements for makeup of membership of the committee.) An ethics committee or, as it is more commonly known, an institutional review board (IRB) is charged with reviewing the informed consent process, appraising the balance of the risks to human subjects with the benefits to either them or society at large, and ensuring the equitable selection of subjects. An IRB must carry out these duties based on a thorough assessment of all aspects of the research design and systematic consideration of alternatives. In view of these and many other federal regulations, institutions (e.g., universities, hospitals, and private research firms that receive federal money) must have IRBs in place and must have procedures for determining research misconduct and conflict of interest, as well as training programs for ethical issues for all researchers who deal with human subjects (and animals). The U.S. Office of Research Integrity reviews and monitors the work of IRBs and pays particular attention to whether institutional policies for addressing charges of research misconduct are in line with federal regulations.

Ethics in Teaching

In one obvious sense, the question of ethics in teaching is more straightforward than complex. The ethics to be followed are simply those of the controlling body, or authority. So if one is teaching in a faith school, the conduct of teaching is informed by the ethics of the religion in question: Catholic, Episcopalian, Muslim, Jewish, and so on. If one is teaching in a state school, the ethics are those authorized

explicitly or implicitly by the state: explicitly through a body of prescriptions and proscriptions, or implicitly through curriculum and assessment requirements that promote compliance with certain practices rather than others. Variants of a state-authorized ethics of teaching are to be found in democracies as well as in totalitarian countries, in local education authorities as well as in nationwide educational systems.

In the above account, the ethics of teaching as a practice are to be determined less by teachers themselves than by major institutional interest groups. These latter have historically included religious bodies, political parties, state bureaucracies, and business interests. More recently, they have also included cultural, ethnic, linguistic, and parental groupings. Indeed, struggles over the control and the ethical tenor of education by bodies other than educational practitioners are among the most prominent themes in the history of Western education. This entry examines the sources and justification of ethics in teaching, the development of practitioner codes for teachers, and the place of formal codes of conduct in the field of education.

A central assumption in the historical struggles over the control of education, and one that helps explain the pattern they have taken, is that teaching as a practice does not have an inherent ethics of its own; or that if it has, such an ethics remains subordinate to the ethics of a superior, controlling body. Here, however, the ethics of teaching remain essentially contestable, bound as they are to the "philosophy of life" of contending parties or individuals. Such contestation is likely to be chronic unless one or another of the contesting parties becomes the stronger party by securing political power.

Following this account to its logical conclusions, it would mean that there is no significant sense in which an ethics of teaching might be comparable with the ethics of other practices, such as medicine, nursing, or engineering, for example. Of course, in few, if any, practices, "Can practitioners themselves be the sole arbiters of the ethics of the practice?" But where the practitioners are a minor or unheard voice, questions arise about the coherence and defensibility of the goals the practice exists to serve.

This would be a rather cheerless conclusion to draw for a practice whose origins *as a practice*, at least in Western civilizations, granted substantial autonomy to educators. In classical Greece, the schools of the Sophists on the one hand and the more participatory Socratic learning environments on the other were *both* free from control by a superior body. That is not to say that either form was free from external appraisal. The worldly ethical orientations of the Sophists' schools seem to have enjoyed unconstrained scope in Greek society. In contrast, the ethic of critical and self-critical inquiry practiced in Socratic educational circles eventually brought trouble on Socrates's head and on this form of education. The loss here was to become an enduring one, as a Socratic ethical orientation was to become more an eclipsed than a defining feature of education in Western civilizations. The ascendancy of Aristotelian and Platonist (more precisely neo-Platonist) influences became decisive in the educational institutions of Western Christendom. A Platonized Christianity became, in effect, the stronger party, and remained so. This curtailed the possibilities for the rise of a tradition of intrinsic ethics in teaching.

Following the publication of Jean-Jacques Rousseau's *Émile* (1762), Immanuel Kant's essay of 1784, "What Is Enlightenment?" voiced a further rebuke to a paternalistic ethics in education, castigating "the guardians who have so benevolently taken over the supervision of men." Kant declared, "Enlightenment is man's emergence from his self-imposed immaturity . . . the inability to use one's understanding without guidance from another" (p. 1). Echoes of this emancipatory note feature in the writings of Johann Heinrich Pestalozzi, Friedrich Froebel, John Dewey, and others, where elements of an intrinsic ethics of teaching are discernible, sometimes prominently so. Yet such writings—even Dewey's—do not make the ethics of teaching an explicit theme of a major work.

Richard Peters's major study of 1966, *Ethics and Education*, attempts just this. In seeking a universal justification for educational actions, Peters closely analyzes concepts like knowledge, understanding, cognitive perspective, equality, freedom, respect, authority, democracy, punishment, and discipline. He also reviews theories of justification like naturalism, intuitionism, and emotivism with a view to advancing his own positive theory, applying Kantian reasoning to ethical concepts in education and seeking to justify them in a universal sense. For instance, in relation to equality in education, he writes, "The general principle of no distinctions without differences is a presupposition of practical discourse, or that it is presupposed in any attempt to determine what ought to be done" (p. 121). Helpful as this approach might be as a general orientation (it would apply as much to politics, business, or public

administration as to education), it is not an ethics of teaching. An ethics of teaching, like an ethics of nursing or of engineering, is in the first place a *practitioner ethics*. It is linked inextricably to the goals of the particular practice in question. Peters clouds this point by claiming that "education raises no philosophical problems that are *sui generis*" (p. 17). In other words, education raises no ethical issues that aren't also raised in other walks of life. Even if one grants this claim, the more central issue for any practice lies in the *manner* in which ethical issues arise within the practice, and also in the *relative weight* to be given to different ethical principles when they come into conflict within the conduct of the practice. There are important differences between one practice and another on this, each practice being informed in the first instance by the coherence of its own central goals.

At a political level, many countries in recent decades established statutory teaching councils, or "colleges of teachers." Such bodies approve and publish ethical codes for teaching, and they mark a historic advance in establishing the ethics of teaching as a substantive domain. The formal character of such codes enables them to serve well as regulatory instruments, as for instance in providing clear criteria for fitness-to-practice investigations. But this formal character also gives primacy to an ethics of duty over an ethics of justice, of care, of vigilance, and so on in the conduct of teaching. It thus tends to favor compliance over deliberation among practitioners. At a philosophical level, theories of ethics do something comparable if they seek to furnish an ethics of teaching. For instance, Nel Noddings's instructive work *The Challenge to Care in Schools* (1992) gives primacy to an ethics of care, which provides more fertile inspirations than an ethics of duty for the actions of practitioners. But its priorities may yet deflect attention from other kinds of considerations that also need to be given weight in the actions that build vibrant, just, and safe learning environments.

Where a truly productive ethics of teaching is concerned, it is necessary that the deliberations and decisions of practitioners, including educational leaders, are afforded some promising pathways and defensible grounds for action. The main emphasis of such an ethics would not be on the alignment of practice to one or another ethical theory. Rather, it would be on the illumination of deliberations and decisions in *a context of specific educational action*—for instance, when principles of care conflict with those of justice in the assessment of students' work, or where there are recurring tensions between concerns for quality and for equality in building and sustaining fruitful learning environments. Such deliberations would be informed in the first instance by some coherent articulation of the central goals of education as a practice in its own right. That is to say that an ethics of teaching is a less than coherent notion unless education itself as a human undertaking and the practices of teaching that promote the undertaking are conceived of as substantive rather than subsidiary.

Ethnicity and Race

Human groups are invariably defined by their borders. From families to states, all groups do elaborate work mixing fact, fear, and fancy while deciding who they are by imagining who they are not. Racial/ethnic groupings are systematically arbitrary:

They easily could be otherwise, but their borders are often strictly enforced and correspondingly volatile. Certainly, racial/ethnic borders figure large in struggles for equal access to economic and educational resources. Late-20th-century inquiries into how they operate—or who they operated on—have shifted focus from the essential characteristics of the groups to the dynamics of power and privilege along the borders to which they must adapt. The focus has shifted from what the groups know, believe, or desire to the circumstances under which they must make their way.

Racial/ethnic borders usually divide groups by access to power. The less powerful have articulated the duality of their situation in ways the more powerful rarely recognize. In *The Souls of Black Folk* (1903), W. E. B. Du Bois reported that White America

> yields him no true self-consciousness, but only lets him see himself through the revelation of the other world. It is a peculiar sensation, this double-consciousness, this sense of always looking at oneself through the eyes of others, of measuring one's soul by the tape of a world that looks on in amused contempt and pity. (p. 3)

Sixty years later, in *The Fire Next Time*, James Baldwin reworked the point: That without White people, there would be no "Negro problem" and in fact no "Negroes in this country—[as] Negroes do not, strictly or legally speaking, exist in any other" (Baldwin, 1962/1995, n.p.). Racial/ethnic categories are reciprocally defined. Groups develop identities—and counteridentities—dependent on the groups around them. It is a mistake—or an act of violence—to categorize racial/ethnic groups in essentialist terms.

The key terms have been hundreds of years in the making. Excited by traveler accounts, medieval Europe imagined the other side of its distant borders populated with grotesque human beings: the *homo monstrous*. In the mid-1700s, Carl Linnaeus attempted taxonomies of all living things. He broke humans into five races: four defined by continent, skin color, and personality traits, and then a fifth, a catch-all category for leftovers: the *homo monstrous*. The first four designations—European, African, Asian, Amerindian—fill the commonsense categories of kinds of people to this day, and the stereotypes Linnaeus tacked on are unfortunately still recognizable: European (sanguine, inventive, and driven by law), African (phlegmatic, indolent, and driven by whim), Asiatic (melancholy, severe, and driven by opinion), and Native American (choleric, obstinate, and driven by custom). His fifth race disappeared from serious accounts of human variation, although *homo monstrous* has survived in the shadows of the other four, ever ready for political intrigue, with each race potentially monstrous to the others.

Linnaeus took a strong hold on Western thought. Even the most liberating thinkers—David Hume and Immanuel Kant—speculated, with unreliable information, on the inabilities of various races. Other thinkers—Gottfried Leibnitz on Chinese philosophers in 1699 and Henri Grégoire on the achievements of people of African descent in 1808—used the same stock of facts to intuit what might be wonderful across racial borders. Either way, the fundamental assumption—that there are categories of people with inherently differential capacities for cultural accomplishment—went unquestioned. After Linnaeus, race became a scientific fact; after Charles Darwin, an evolutionary fact; and after Gregor Mendel, a genetic fact. Europeans investigated the facts: The number of races and their potentials were disputed, differential intelligence (a rare consideration before modern European cultures) became a scientific and biological fact, and White people dreamed of measuring intelligence across groups.

By 1900, racial theories celebrating White people and the rise of European civilization were countered by fact-filled arguments. Cross-cultural research became the center of antiracist inquiry. Franz Boas organized anthropology into four fields—cultural, physical, linguistic, and archaeological—each used to produce data-driven comparative inquiries into human capacities tuned to the affordances and constraints of various environments. For Boas, race, language, and culture are not inherently tied to each other, and any human being can, with proper socialization, participate fully in any culture. His major work, *The Mind of Primitive Man* (1938), showed that any human group, of any physical type, with any language, in any culture, can raise individuals rich in potential.

Across the 20th century, the scientific status of race declined, while racism remained rampant. Biologists no longer treat race as a variable in human potential, but biological systematics are generally irrelevant to racist convictions. Racists can focus on arbitrary phenotypic traits—skin color, hair type, and nose shape—in whatever percentages they please: Only a hint of African descent can make

a person Black in the West; only a hint of Caucasian descent can make a person White in Africa. Wobbly categories feed the prejudices with which they are used, and descriptions of race groups say more about their authors than about the people inscribed.

Boas critiqued scientific racism by finding more variation within than across named race groups. His findings were based on caliper measures of body proportions; mid-century anthropologists added similar conclusions with serological data, and geneticists have confirmed the results with data from inside cells.

While racial categories were losing scientific status, criteria for building hierarchies of cultural achievement came into question. Boas's era worried about how often and why civilization emerged in the ancient world. (Answer: six times; as to why: auspicious ecological conditions fitted to the right toolkit for a long time.) The original question–answer pair promised a celebration of the West's evolution from savagery and barbarism (loaded terms of the day), but by mid-century, *civilization* became a technical term for organizational achievements—large urban centers, a state apparatus, armies, hydraulic works, monumental architecture, craft specialties, a priestly class, and careful record keeping—regardless of intellectual or moral progress. Civilizations produced advanced capacities for and a record of cruelty and destruction. In contrast, the opposite of civilization, the so-called primitive, gained positive value.

For 50 years, race and ethnicity researchers have relied on modes of analysis similar enough to allow the term *racial/ethnic*. The terms also can be contrasted by the relentlessness of color racism and the situational flexibility of ethnic boundaries. So it is noteworthy that Irish and Jewish populations were once classified as non-White and transitioned (unevenly) to White racial status in the 20th century, but not noteworthy that, as White ethnics, they can negotiate—even ignore—their borders; a simple change of clothing, surname, or dialect might allow an identity shift. Another contrast is the ubiquity of interracial degradation and the occasional enormity of interethnic violence; the former, however unpleasant, can maintain a steady state, while the latter explodes more often into genocidal warfare.

Reconfigured ethnic borders can be surprising. Two thirds of the earth's population, one third of its languages, and a few of its races (however classified) live in Asia. Imagine the diversity of racial/ethnic categories that could be applied to populations from Pakistan to Japan. Now imagine them under a single ethnic category in one place: Asian American. In *Reading Asian American Literature* (1993), Sau-ling Wong embraced this multiracial–cultural–national–linguistic ethnic union for its irony and political import. Asians were the only people denied entrance to the United States on racial grounds. Although the "Oriental" racial tag has been suppressed, new circumstances have brought the various groups together. In the new politics of ethnic categories, says Wong, timing and calibration are what counts. Even the borders isolating and protecting White people are changing, conversationally anyway, and sociolinguists have been documenting how White people must explain themselves in accord with current racial/ethnic arrangements. If borderlines between race groups soften, new ethnicities can emerge.

Shifting categories aside, ethnic borders can be continually renewed under diverse conditions across centuries. Borders can be stored in seemingly invisible places. Jewish people are not required for anti-Semitism to inflame political discourse in modern European nations (and in other, surprising, places, from modern Japan to villages in Mexico). Deep ethnic tensions in Soviet bloc countries disappeared under a half-century of strong central control only to explode under postsocialist conditions. Protestant–Catholic troubles in Northern Ireland fluctuate with unemployment rates but never disappear from neighborhood associations and marriage patterns.

Economic and power differentials dividing groups by locale, purpose, and sentiment are more constant than ethnic identities. Named groups can change, but their borders remain. When Polish, Italian, and Irish Catholic children attended their own schools in northern American cities before World War II, they had to run—not walk—through each other's neighborhoods, but after the war, the same groups moved to mix-and-match postethnic suburbs. Among the circumstances: a few million Latino and African American migrants moving to the cities. White ethnics are replaceable if others fill their slots when conditions organizing borders are more important than the characteristics of the people divided by them. When British geographers drew arbitrary borders in Ireland, India/Pakistan, Cyprus, and the Middle East, they cut through delicately nuanced groupings that had maintained difficult situations without uncontrolled violence, and the price has been heavy.

Ethnic groups and their tensions—schoolchildren escaping neighbors; terrorists in Ireland, India, and the Middle East—arise in resistance to and in cahoots with surrounding conditions extending to far-off points of contact and control. Disputed

borders, even those not in the highlights in global news—between spatially stable and transhumant groups in southern Iran, and between Moslem seafarers, pagan farmers, and Christian overseers in the war-torn southern Philippines—originate in conditions rooted in distant markets. Ethnic relations are increasingly tuned to how capital and culture work their way and sway around the world. In their book *Ethnicity, Inc.*, John and Jean Comaroff (2009) have gathered examples of a worldwide craze by which ethnic groups are selling their "natural" identities to tourists, nongovernmental organizations, and entertainment venues under desperate conditions that have made selling cultural products and the "simulacra of ethnicized selfhood" one of the few means by which members of some ethnic groups can survive. If 20th-century analyses have shifted from essential traits to local conditions edging ethnic finery into high visibility and contestation, 21st-century inquiries add accounts of global capital and population flows as the widest contexts for group conflict and commodification.

A final question: Given the vicissitudes of racial/ethnic phenomena, how can they consistently correlate with school success and failure? An answer: Racial/ethnic tensions, in tandem with poverty, are built into the daily practice of schools. The very institution designed to make borders unimportant has been co-opted into enhancing them. The shift from essentialist to more contextual views of racial/ethnic borders reformulates minority school failure by eschewing questions about what is wrong with individual children not learning to answer questions about how borders get re-created in schools.

Categories for racial/ethnic groups are tightly tied to measures of social class and educational risk, often stated in an established, but misleading, three-step order. First, racial/ethnic identities are defined as traits given at birth and made negatively consequential by prejudice and unequal conditions. Second, class is defined as mostly undesirable traits socialized into children with limited opportunities. Third, because racial/ethnic and class inequities are thought to suppress normal growth and development, minority and poor children are most at risk of school failure. This diagnosis lives in cultural preoccupations feeding a general bias: White middle-class lives offer children the best of all worlds. The bias leads to a disappointing policy of victim blaming the oppressor. Fix the children and racial/ethnic and class barriers to democracy can be toppled one person at a time.

An alternate three-step theory is possible. First, human variation offers a complex quilt of physical traits that can be dissected and highlighted to various ends. Second, because jobs, money, education, and degrees are the stuff of privilege, class can be redefined by access to resources regardless of the traits of individuals. Third, risks built into high-stakes politically manipulated win/lose contests like norm-referenced tests are a way of making racial/ethnic and class differences legitimate. This alternative order shapes a blame-the-oppressor bias: Because schools suppress normal growth and development for everyone in favor of preparation for tests well tuned to the established order, immigrant, minority, and poor children—being less receptive to the arbitrary but standardized curriculum—are most at risk of failure. The message to educators also changes: Failing children do not need to be fixed as much as they need, as does everyone, a learning curriculum connected to reality and eventual employment.

By this reformulation, the analysis of race and ethnicity in education can focus less on *what* traits correlate with what outcomes and more on *how* school outcomes are made to correlate with the categorically flimsy data of ever-shifting, ever-shifty, racial/ethnic traits. New analyses should show *how* racial/ethnic borders get done: by what work, by what schedule, in response to what demands, and how far away in the world?

Evaluation of Educational and Social Programs: Models

Program evaluation is the systematic determination of a program's value (merit or quality, worth, or significance). It is a form of disciplined inquiry that involves careful design of a study to take into account program objectives and outcomes as well as issues of greatest concern to stakeholders, rigorous procedures to gather credible evidence of program value, and transparent, justifiable processes for linking evidence to evaluative conclusions. This entry discusses several approaches to program evaluation: results-based approaches, social value approaches, process-oriented approaches, stakeholder-oriented approaches, and program-theory approaches.

An educational or social program is an organized collection of activities and processes aimed at achieving particular objectives, for example, an early childhood intervention program implemented statewide providing a range of educational, medical, and social services to enhance young children's development and learning and to provide support services to families; an after-school science program for middle school children delivered in an informal learning setting such as a Boys and Girls Club designed to advance science learning as well as attitudes toward science; a case management program implemented in a large urban city intended to prevent recurrent homelessness in people with mental illness; career academies that operate as small learning communities within low-income high schools providing academic, career, and technical courses and workplace opportunities in cooperation with local employers; and a high-intensity supervision program for probationers at risk of probation violation designed to reduce the incidents of rearrest. Programs vary in complexity depending on their level of maturity (i.e., a relatively new program versus one that has been operating for several months or years); the social political circumstances in which they were conceived (i.e., the program's political profile, the types and degree of risk inherent in the program); the social, political, and cultural contexts in which they are implemented; the number of sites in which they are offered; the number of participants involved; and the range, complexity, and duration of activities that constitute the program.

Program funders and stakeholders (parents, program managers, direct service providers, the general public, etc.) are often interested in whether a program has had its intended effect(s) and whether those effects were achieved in a cost-effective way. They may also be interested in how a program might be improved, whether it was perceived as worthwhile by program participants, whether program goals were reasonable and worthy of pursuit, and whether effects other than those intended resulted from the program.

Evaluation Models

It is questionable whether the term *model* is the correct designation for the extensive variety of evaluation approaches that scholars and practitioners have developed in the past 40 years. If the term *model* is used in the sense of a scientific model—an approximation or representation of a real system or phenomenon—then what we find in evaluation are not models per se but rather different interpretations of and perspectives on the purpose of evaluation and how it should be conducted. Thus, the terms *framework*, *orientation*, or *approach* are probably more semantically correct designations. While there is considerable disagreement on how these many approaches should be classified, generally speaking, they are distinguishable in terms of what they put forward as the primary organizing principle for program evaluation. The families of approaches presented below are not mutually exclusive—there is

nothing in principle preventing the combination of evaluation approaches in a single evaluation study. What constrains the choice of approaches are practical matters including costs of implementing a particular approach in view of available funds, evaluator experience and preferences, timelines, contract requirements as reflected in an evaluation's terms of reference, and so on.

Results-Based Approaches

What this collection of approaches has in common is a primary focus on (1) whether stated program goals, targets, or objectives were met—this is often referred to as outcome evaluation or outcome monitoring, or on (2) program effects or outcomes regardless of whether they were intended or unintended—this is commonly called impact evaluation. Some evaluators concerned with this second focus practice what is called "goal-free evaluation" and argue that programs ought to be evaluated not on what they are trying to do (i.e., not on what their stated goals are) but on what they actually accomplish.

Impact evaluations are primarily interested in the causal question in the generic form "what is the effect of a known cause," where the cause is the program in question. Impact evaluations are often designed to test the counterfactual—that is, a comparison between what happened and what would have happened in the absence of the particular program.

Impact evaluation approaches differ in the way the cause–effect relationship is examined. Some treat the program as a black box and focus on mean differences between the group of individuals who went through the program and the group that did not (or who received some alternative program). Others endeavor to get inside the black box and explain the causal mechanisms by which the program works (see the discussion of program-theory approaches below). Still other results-based approaches rely on systems thinking and complexity science to grasp how program effects are to be understood and explained. System effects or system–context interactions are of particular interest to evaluators working in fields like public health where the effects of a given public health intervention (e.g., a smoking cessation program or an obesity prevention program) are not necessarily a direct result of a single intervention but of the complex interaction of that intervention with other interventions, health policies and practices, the norms and practices of service-providing organizations, client behaviors, and so on in a given community.

Although referred to as research rather than evaluation, comparative effectiveness studies in the field of health care are a results-based evaluation approach. These studies compare the effects of two interventions (therapies, drugs, surgeries, means of health care delivery, etc.) to determine which works best for particular patient populations and what benefits and harms are associated with each intervention.

Social Value Approaches

In public and private sectors, there is strong interest in the development of quantitative indicators (metrics) that reveal the social or public value of investments in programs. However, it is widely acknowledged that there is no agreed-on, authoritative definition of social value and that metrics used to assess social value often conflate measuring social impact with demonstrating accountability to external stakeholders. Some scholars argue that real-world problems and the programs (interventions) designed to address them cannot be captured with the kind of precision that measures of social impact demand. It is often quite difficult to quantify let alone monetize the benefits of various kinds of social programs (e.g., the benefit of living in a more just society; the consequences of antiracist programs).

The most common social value evaluation approaches are cost–benefit and cost-effectiveness analysis, but there are dozens of others, including ex-ante stated preference analyses, that ask people what they would pay for a given service or outcome; social return on investment assessment; and value-added analysis, as has been employed, for example, to determine how much teachers add to the overall quality (academic performance) of their students. In the field of development evaluation, quality-of-life indicators, such as the United Nations Development Program's Human Development Index or the Organization for Economic Co-operation and Development's Better Life Index, are used as proxy measures in evaluating the collective outcome of multiple social and educational interventions affecting the general well-being of societies as a whole.

Process-Oriented Approaches

These approaches are focused on evaluating program implementation and are typically concerned

with what is done, when, by whom, to whom, and how well. Evaluations of this kind pay careful attention to

- describing the operating environment or context(s) of a program;
- the actual processes involved in the program (e.g., planned and unplanned participant interactions, extent and nature of participation, nature and duration of program activities such as use of technology, training, workshops, or counseling); and
- problems encountered in program delivery, modifications made in original delivery plans, the addition of new program objectives, and so forth.

Evaluations of this kind can be used to determine the feasibility of a program during a pilot stage, whether a program was implemented as planned (often a serious concern in programs with multiple sites where local factors or circumstances can either facilitate or interfere with the reliable implementation of a program), and/or program effort. Process evaluation can provide decision makers with information useful in improving, refining, modifying, and, in some cases, discontinuing a program by delivering information on a program's circumstances or situation (changing conditions that affect the implementation of a program) and on program performance (progress on achieving intended results).

Progress monitoring is an example of a process-oriented approach. Take, for example, the case of a school district that implemented a response to intervention model (according to the National Center on Response to Intervention, this involves designing and implementing a process to identify students at risk for poor learning outcomes, monitor student progress, provide evidence-based interventions, adjust the intensity and nature of those interventions depending on student response, and identify students with learning disabilities or other disabilities). The district might develop a progress-monitoring system to determine whether all teachers are successfully implementing the response to intervention model across all classrooms in the district.

Stakeholder-Oriented Approaches

Stakeholders in an evaluation include individuals and groups with an interest in program outcomes. They include individuals involved in operating the program (e.g., program managers, service providers), individuals (or agencies) funding a program, individuals served by the program (program beneficiaries), individuals or collectives indirectly affected by a program (e.g., citizens in a community receive indirect benefits because the community has a vigorous program to help women who are victims of domestics abuse), and individuals who will use the evaluation to decide something about the program. Stakeholder-oriented approaches are first and foremost concerned with how an evaluation includes and serves these groups of individuals. It should be apparent that deciding just who among these stakeholders should be involved in evaluation, and how, is a topic of considerable discussion and debate among advocates of stakeholder-based approaches to evaluation.

This family of evaluation approaches includes those that are referred to as participatory, collaborative, empowerment oriented, client or stakeholder oriented, appreciative, and responsive. Distinguishing characteristics of these approaches include a focus on locally relevant evaluation questions, efforts to be directly responsive to issues and concerns of the most immediate stakeholders, and the involvement, to varying degrees, of stakeholders in the evaluation. In collaborative approaches, evaluation becomes a shared responsibility of the evaluator and key stakeholders. In participatory and collaborative evaluation approaches, stakeholder participation can range from being active in the design of the evaluation to roles in the collection and analysis of data as well as reporting. Participatory evaluation can also take two forms: one more or less practical and utilization oriented and another more or less transformative and focused on empowerment of participants in the evaluation. Stakeholder-based approaches to evaluation can be used to build evaluation capacity with an organization (i.e., a "culture" of evaluation) and to enhance and sustain critical, reflective organizational learning. Responsive evaluation orients to the uniqueness of a program in context and the plurality of views, expectations, and standards that attend program performance; its essential feature is attention (responsiveness) to critical issues and concerns raised by those most familiar with a program.

Culturally responsive evaluation has arisen in recent years as an important development in stakeholder-based approaches. It argues that culture defines the context in which particular conditions come to be defined as social and education problems,

the ways in which programs are developed as solutions to those problems, the way programs are theorized (see below) and implemented, and the way in which evaluation evidence is gathered and findings are interpreted. Culturally responsive evaluation strongly emphasizes that evaluators must not only be cognizant of these aspects of culture in evaluation but also be competent in designing and implementing an evaluation that takes these aspects fully into account.

Program-Theory Approaches

Program-theory approaches are concerned with how a particular program actually works—they focus on developing an explicit theory of how a program is expected to bring about desired change and testing assumptions that underlie such a theory. These approaches to evaluation endeavor to get inside the black box of a program to understand how various components of a program work in concert to produce desired outcomes. A program theory is often graphically represented using a logic model (also referred to as a program matrix, theory of change, theory of action, or logical framework). The model displays logical links among program inputs (human, financial, and organizational resources directed toward the program), activities (processes, events, and actions such as recruitment, screening, workshops, training, counseling, appraisals, assessments, etc., that constitute program implementation), outputs (direct products of activities such as types, levels, and targets of services), and short-term, intermediate, and long-term outcomes (specific changes expected in program participants' behavior, knowledge, skills, status, level of functioning, etc.).

These models can be both descriptive (how the program actually works) as well as normative (how the program is supposed to work). Program-theory approaches use such models to guide a variety of evaluation activities and decisions, including identification of program dimensions most critical to program success, selection of appropriate measures and observations, identification of successes or failures in various aspects of program implementation, and interpreting evaluation findings. In many versions of program-theory approaches, stakeholders are directly engaged in the process of developing the program theory as an essential step in evaluation planning. Some scholars advocate combining impact evaluation with a theory-based approach to create theory-based impact evaluation. They argue that such an approach enhances the policy relevance of an evaluation because it becomes possible to understand the reasons for differing levels of program participation and the processes responsible for affecting changes in the behaviors of participants. A particular version of theory-based impact evaluation known as realist evaluation holds that programs "work" for different people in different ways and thus an evaluation must uncover the links between mechanisms that trigger individual behavioral change and contexts that enable or constrain such mechanisms; hence, context + mechanism = outcome.

Evidence-Based Policy and Practice

The idea that professional practices such as education should be based on or be informed by research evidence has, over the past two decades, become influential in policy, practice, and research in many countries around the world. The aim of this entry is to clarify what the idea of evidence-based policy and practice entails, to trace its rise in the field of education, and to discuss a number of critical issues that have been raised in the literature.

The Idea of Evidence-Based Education

The suggestion that education should become an evidence-based profession emerged in the 1990s. In part, it resulted from concerns about the quality and significance of educational research, where it was argued that such research was not generating useful knowledge. It also arose out of concerns about educational practice, where it was argued that much of what was going on had no basis in research evidence. The idea that research evidence should play a role in professional fields such as education is not without reason, because professions, unlike other areas of work, lay claim to having specialized knowledge and skill. The question, therefore, is not so much whether or not evidence should play a role in education but what kind of role it can play and also what role it should play.

Opinions are clearly divided on this issue. The most vocal arguments have been made by those who argue for a very particular kind of evidence—usually referred to as evidence about "what works"—and for the use of one specific research design, namely, the large-scale randomized controlled trial. The key idea of this design, which stems from research in fields such as medicine and agriculture, is that the effectiveness of a certain intervention or treatment can be tested by comparing a treatment group with a control group and by randomly allocating the treatment. If the treatment shows the expected effects in the treatment group, but there is no change in the control group, it can be assumed that the treatment or intervention works.

Many proponents of the idea of evidence-based education not only have argued that such evidence might play a role in educational policy and practice but also have taken the stronger position that educational policy and practice should be based on such evidence. Some have even argued that teachers and policymakers should not be allowed to do anything for which there exists no conclusive scientific evidence of its "working." A key question here is whether scientific evidence should ultimately *replace* professional judgment and decision making or whether it should play a role in informing such judgment and decision making. This is sometimes captured in the distinction between evidence-based education and evidence-informed education.

What Works: For What?

While the idea that education should be based on evidence about "what works" sounds attractive, and while it could be argued that questions about what works are at the forefront of teachers' everyday concerns, the idea that teachers just need to implement scientific knowledge about "what works" in order to be good teachers is both simplistic and misleading.

One problem with the idea of "what works" is that it tends to forget to ask the question what a particular way of doing is supposed to work *for*. The problem here is not only that discussions about "what works" in education tend to pay little attention to the more difficult question what education is supposed to work *for*. More important, it is also that educational actions and activities never "work" or aim to "work" in relation to one particular outcome or result but always in relation to a number of different areas or domains. It is, after all, not only that we want our students to acquire particular knowledge or master particular skills. At the very same time—if, that is, our overall aim is not that of indoctrination but of education—we also want our students to be able to think and judge for themselves and to develop a range of different personal qualities such as empathy, curiosity, compassion, or a democratic attitude.

While particular educational strategies might "work" in relation to one of these domains or with regard to one particular outcome, it is unlikely that such a strategy will also "work" in relation to other domains. The multidimensional nature of educational purpose (see Biesta, 2009), thus, already creates a problem with the idea that good teaching is simply a question of implementing evidence about "what works." Judgment is needed not only to determine what education needs to work *for* but also to find a meaningful balance between the different domains in which education seeks to function, particularly with regard to the trade-offs when achieving results in one domain may go against achieving results in another.

Judgment is also needed because the means of education are not neutral with regard to the ends—which, in more everyday language, refers to the fact that students not only learn from *what* we teach them but also from *how* we teach and approach them. Even if research were able to provide strong evidence that a particular way of doing may bring about particular effects, there is still the question whether this way of doing is educationally desirable. There may well be conclusive evidence that corporal punishment is the most effective way to modify someone's behavior, yet we may still decide not to act on this evidence because we do not want to teach our students that corporal punishment is ever justifiable.

The Limits of the Medical-Agricultural Model

A second problem with the idea of evidence-based education has to do with the fact that, at least in its "what works" form, it takes its conception of research—and by implication also its conception of education—from the fields of medicine and agriculture. Whereas randomized controlled trials might make sense in such domains—although even there, questions about what interventions and treatments are supposed to work *for* is a relevant question—simply transplanting such an approach to the field of education is not without problems. The main problem has to do with the fact that the fields of medicine and agriculture deal with physical processes of push and pull, whereas education is fundamentally a social process of communication, meaning, and interpretation. This also shows why it is a mistake to think of teaching as an intervention or treatment; the "recipients" of our educational efforts are not random objects that we intervene on but human subjects in their own right who, as students, have to make sense of what their teachers say and do. It is therefore only in cases where we would conceive of education as the external modification of behavior that the medical-agricultural model might make some sense. Yet most educators would see that as a case of indoctrination rather than of education, precisely because it conceives of students as objects of our interventions and control rather than as human subjects on their way to independent thought and responsible action.

What Kind of Evidence?

A final point has to do with the idea of evidence itself and, more generally, with the question what kinds of knowledge might be of benefit to educational practice. In the research and policy literature, the emphasis is exclusively on technical knowledge, that is, knowledge about relationships between particular actions and the consequences of those actions. While such knowledge can be useful in guiding educational actions, even then it is important to acknowledge that any knowledge we gain about relationships between actions and consequences can at most provide us with possibilities—it can tell us what has worked in the past under specific conditions and in relation to particular individuals or groups—but not with certainty about what will work in the future. Added to this is the fact that educational research and scholarship not only generate insights in relationships between actions and consequences but also provide different interpretations and understandings of educational phenomena. While such knowledge does not provide us with a "base" for educational action, it can nonetheless be highly useful for educators as it helps them see their practice in new and different ways. This can contribute both to understanding particular problems or issues in a new light—think, for example, how sociological research has deepened our understanding of the ways in which education reproduces social inequality—and to new and different ways of working. To suggest that research should provide only technical knowledge and should operate only through randomized controlled trials thus takes a very narrow view of the actual contribution research and scholarship can make to educational policy and practice.

Conclusion

While, at first sight, it may sound obvious that educational policy and practice should be based on scientific evidence about "what works," a closer inspection indicates a far more limited role for evidence in education than what proponents of evidence-based education often seem to be after.

Evolution and Educational Psychology

When psychology began to develop as an academic field in the late 19th century, evolutionary ideas were much in vogue. As a result, virtually all of the first generation of American psychologists, like many elsewhere, adopted an evolutionary approach to the field. An evolutionary conception of mind led William James (1890/1950) to argue that consciousness "exists" (as a function, not a thing); it had practical, adaptive value:

> Man, we now have reason to believe, has been evolved from infra-human ancestors, in whom pure reason hardly existed, if at all, and whose mind, so far as it can have had any function, would appear to have been an organ for adapting their movements to the impressions received from the environment, so as to escape the better from destruction. Consciousness would thus seem in the first instance to be nothing but a sort of super-added biological perfection—useless unless it prompted to useful conduct, and inexplicable apart from that consideration. (pp. 23–24)

James's student, G. Stanley Hall, influenced by Charles Darwin and by Ernst Haeckel's notion that "ontogeny recapitulates phylogeny" (individual, including embryonic, development retraces the evolutionary development of the species), helped found the child study movement and the field of developmental psychology. John Dewey, one of Hall's students, adopted a neo-Hegelian approach to psychology, which focused on cultural rather than biological evolution, altering his interpretation in a more naturalistic (Darwinian) direction after reading James's *Principles of Psychology* (James, 1890/1950). James Mark Baldwin also adopted an evolutionary approach when considering the functional selection of a child's behavioral repertoire within an evolving sociocultural context. Baldwin, in turn, influenced Lev Vygotsky, Alexander Luria, and Jean Piaget.

Evolutionary Philosophy

Evolutionary ideas were in some cases generalized into overall philosophies, or philosophical approaches, in which everything was considered from an evolutionary standpoint. Herbert Spencer applied his notion that things evolve from simple homogeneity to complex heterogeneity to virtually every subject. Charles S. Peirce developed a much more rigorous evolutionary philosophy involving the interplay of chance, continuity, and the statistical tendency to form law-like "habits." Dewey and George Herbert Mead drew on Peirce, developing their own evolutionary philosophies. Among the things that evolved were acts themselves, which were viewed as temporal developments rather than given entities.

One of the attractions of an evolutionary approach was that it promised to help resolve difficulties created by Cartesian dualism. Descartes's conception of mind and body as categorically different entities, bodies being physical machines and souls or minds metaphysical entities capable of abstract reason, made the body unintelligent and the mind disembodied. It also created insuperable difficulties in understanding how two completely different kinds of things could interact in the individual. An evolutionary approach promised to restore continuity by viewing human mental functioning as a refinement of simpler processes evident in social animals or even simpler organisms or natural processes and the body as more end directed and, thus, implicitly more intelligent than a machine. In effect, reason became more practical and practice more reasonable when viewed from an evolutionary perspective.

Growth of Differential, Comparative, and Developmental Psychology

As Boring (1929) notes, three subfields of psychology important for education developed out of these initial concerns. Differential psychology—the psychology of individual differences—emerged from

the concern of Darwin's cousin, Francis Galton, for hereditary differences in "genius." This led to the eugenics movement, IQ (intelligent quotient) testing, and trait psychology. Comparative psychology, concerned initially with studying the mental functioning of different species in laboratory experiments, turned into behavioristic psychology, which focused on learning processes common to rats, pigeons, and humans. Concern for individual ontogeny in an evolving sociocultural context turned into developmental psychology, which tended to focus on universal stages of human development. These three emphases constituted most of educational psychology up to the late 1950s, with the notable exception of clinical or "abnormal" psychology, which was considered beyond the pale scientifically.

Romantic, Survival of the Fittest, and Interactional Conceptions of Evolution

Different conceptions of evolution were also in play at the turn of the 20th century, as are different versions today. In what might be called the "Romantic" conception of evolution, the individual was seen as the source of major change, as in the neo-Hegelian emphasis on the importance of "world-historical" individuals, like Napoleon or biological interest in "hopeful monsters," uniquely different organisms that, if viable, could take evolution in a new direction. A more conservative interpretation viewed change as coming largely from the outside, as individuals are forced to adapt to environmental contingencies over which they have little control. Spencer and William Graham Sumner were among the proponents of such a survival-of-the-fittest attitude in social life, commonly referred to as Social Darwinism. Finally, an "interactional" conception viewed organisms as affecting their environments and as being affected in return, the course of interaction being contingent in each particular case. Dewey, with his emphasis on the interplay of "doing" and "undergoing" and intelligent experimentation to learn how things work, was an important proponent of this approach, as was Lester Frank Ward in sociology.

Subsequent Interpretation

While all three of these approaches were present in late-19th- and early-20th-century debates, the approaches that survived in mainstream psychology, represented by the subfields discussed earlier, can be viewed as the fruits of the more conservative adaptationist interpretation. This may have been, in part, because new developments in physics made it, rather than biology, the dominant field to emulate, giving psychology its often discussed "physics envy." Logical positivism also contributed in emphasizing the verification of scientific laws by inference-free observations. The resulting focus on behavior measured in terms of external norms (e.g., those embodied in IQ tests) on contingencies of reinforcement, or on universal stages of development, made the development of a narrow version of "scientific" psychology easier but truncated psychological understanding by overlooking the ability of organisms in natural settings to alter the contingencies facing them or leave an environment for another they preferred (McDermott & Hood, 1982; Newman, Griffin, & Cole, 1989).

With the coming of the cognitive revolution in the late 1950s, the computer became the new model for the mind, and computer science the new field for psychology to emulate. With more going on "inside" the mind, even though it was conceived as a complex machine, it became less possible or desirable to simply read off performance scores based on external norms. One had to understand inner rules and processes and not just the eventual outcome. This created some evolutionary and developmental difficulties for those adopting a classical symbol processing approach to mind, based on the computer, like Allen Newell and Herbert A. Simon, because to get such a process going, one had to have the basic components in place at the beginning. In effect, one had to have the equivalent of a computer and some basic software already in place for "thinking" to begin. This tended to force cognitive psychologists into forms of nativism, as in Noam Chomsky's argument that human beings are born with an innate "language acquisition device" enabling them to learn syntax, Jerry Fodor's argument in favor of innate mental modules, or Howard Gardner's (1985) claim that each of his multiple intelligences has a given biological substrate. Such accounts tend to be evolutionarily unsatisfactory because they seek to explain the development of mind by asserting that its essentials were already there in the first place.

The discovery of DNA (deoxyribonucleic acid) in 1953 would lead to a renewal of interest in biological ideas; biology has again become a field for psychology to emulate. Evolutionary ideas are also back in vogue, and different conceptions again are in tension. One of the differences between the present debate and that of the first half of the 20th

century is that the individual is less likely to be considered the basic unit of analysis. Developments in cellular and molecular biology have made it tempting to begin at a lower level, such as the neural or genetic level. At the same time, as Bredo (2000) notes, the development of linguistics and the sociocultural sciences, as well as linguistic and social philosophy, make it also tempting to begin at a higher, sociocultural level. (In a sense, the situation can be described as a clash between genetic or biological determinism on the one hand and cultural constructivism on the other.)

The emerging field of evolutionary psychology adopts the first strategy, attempting to explain widely adopted forms of social behavior in terms of lower-level genetic adaptations. Some social behavior, such as altruism, may appear difficult to understand from an individual point of view, for example, because it is apparently irrational; however, as Richard Dawkins points out, it can be understood as rational from a genetic point of view if the survival of sufficient numbers of near kin bearing one's genes is ensured by such behavior. This suggests that cooperative social behavior may be more explicable on genetic rather than individual grounds. Such considerations led E. O. Wilson to argue that human nature consists of predispositions to behave in certain ways as a result of epigenetic rules "built into the brain in the form of a learning bias" (Wilson, 1996, p. 18), leading people to tend to learn certain forms of behavior more readily. This argument is used to support both the notion that human nature is universal and the conservative political point that relatively universal forms of social life, such as traditional gender roles and social hierarchies, persist because they made, and possibly continue to make, adaptive evolutionary sense.

A directly opposing approach argues that individual minds and personalities are products of different cultures and social positions, each of which is evolutionarily unique (like the "hopeful monsters" mentioned earlier). Those from different cultures, or members of different social categories within a culture, such as men and women, are believed to develop categorically different ways of thinking as a result of differing cultural norms and structural contingencies (Maltz & Borker, 1982). Even organic characteristics, such as bone development and musculature, not to speak of literal inscriptions, such as tattoos, may be socially "inscribed" on the person. Thus, rather than one universal form of human nature, or one universal form of reason, there are many essentially different forms of human nature and many essentially different "mentalities." Individual personalities and mentalities are, then, seen as the product of a person's location at the intersection of the groups and categories to which he or she belongs. The obvious political point is that such essential differences should not be ignored or marginalized by assuming that there is only one universal human nature or one universal form of mind or reason.

An alternative to both of these views is, again, some form of interactionism. Unique, multiply potentiated individuals grow up in unique, multiply potentiated social environments, each interacting with the other to create a life trajectory or set of life trajectories. Humans are indeed a distinct species, as emphasized by those arguing for a universal human nature, but what they share most fully are early phases of development, such as sensorimotor skills, that are very similar to the early accomplishments of other species (Scarr, 1983). Specialized adult accomplishments, which should *also* be considered part of "human nature," are among the characteristics that are least widely shared. Something similar can be said about human societies, some of whose ancient cultural elements are shared by virtually all (e.g., cooking with fire), while many newer inventions are not so widely shared. As a result, individuals and societies are neither essentially identical nor essentially different, since their old and new aspects tend to overlap with others to differing degrees.

Conclusion

Rather than arguing about whether individuals or societies are essentially the same or different, then, we could be concerned with how particular individuals may be helped to thrive and develop as a result of their experiences in forms of social life that are themselves being helped to thrive and develop. As Daniel Keating and colleagues put it, we might be concerned with the way "developmental health and the wealth of nations" are related to one another (Keating & Hertzman, 1999). Approached in this way, an evolutionary approach to psychology takes us back to the basic task of education without presupposing a correct answer before one begins.

Existentialism

See Beauvoir, Simone de; Sartre, Jean-Paul

Experiential Learning

It is hard to imagine an effective approach to learning that does not involve the learner in some kind of experience. The idea that knowledge, understanding, or skills could be passively absorbed is the antithesis of good teaching. This is especially true in modern approaches to education, where the goal is to actively engage students and help them to construct learning. Learners are not empty buckets or blank slates, and unless new ideas and new experiences link to previous experience, these ideas and experiences may lack meaning and context. However, if all learning is experiential, the use of the adjective "experiential" to distinguish one kind of learning from another is puzzling. The purpose of this entry is to explore this quandary and to identify the defining characteristics and contentious issues within experiential learning theory and practice.

The philosophy, principles, and practices of experiential learning permeate many diverse approaches to both formal and informal education. The development of philosophical thought about the importance of experience in learning settings has been linked to the Greek philosophers, but it is likely that the earliest humans used a version of "trial-and-error learning," especially as their capacities for reflection increased as cognitive functioning developed. In more recent times, the principles and philosophies of experiential learning underpin pedagogical approaches such as problem-based learning, inquiry-based learning, service learning, and adult education.

Although the terms *experiential learning* and *experiential education* are sometimes used interchangeably, this can be troublesome and the distinction is worth noting. On its website, the Association of Experiential Education (2013) defines experiential education as

> a philosophy that informs many methodologies in which educators purposefully engage with learners in direct experience and focused reflection in order to increase knowledge, develop skills, clarify values, and develop people's capacity to contribute to their communities.

According to this definition, experiential education uses the principles of experiential learning but what distinguishes experiential education is the transactive process between the educator and the student. Clearly, it is possible to engage in experiential learning without the presence or influence of an educator at all. This entry will focus mainly on experiential learning in educational settings and, hence, on the theory and practice of experiential education.

To better understand the educational potential of experiential education, it may help identify some of the defining characteristics of experiential learning. In doing so, I will draw on the foundational work of several theorists, including the well-known educational theorists John Dewey, Kurt Lewin, Paulo Freire, and David Kolb. The work of several recent authors will then be used to critique some of these original ideas and consider the place that experiential education may have in the future. First though, a brief look at the evolution of experiential learning is needed.

Dewey is often described as the father of experiential education, and he summarized his views in his book published in 1938 titled *Experience and Education*. Dewey was critical of traditional approaches to education that were static, and he argued that the educator's role is to provide opportunities to engage in purposive experiences, to help learners reflect on those experiences, and to help them build on past experiences, preconceptions, and knowledge. For Dewey, learning experiences needed to be enjoyable and interesting enough to keep the learner engaged. In his view, not all experiences were necessarily educative; some were potentially aimless or neutral activities, and some were even miseducative in that they diminished learning in the future. Dewey wrote that an educative experience should arouse curiosity, strengthen initiative, and set up desires and purposes that carry the individual over "dead places in the future." In sum, "every experience is a moving force. Its value can be judged only on the ground of what it moves toward and into" (Dewey, 1938/1963, p. 38). Experiential learning was not just serendipitous learning for Dewey, he held that educators should use careful planning, develop extensive background knowledge, and be ready to teach subject matter when required. Being student centered did not mean that the educator relinquished his or her authority or responsibility to guide. A final point about Dewey's approach concerns the tension he noted between the individual freedoms of learners and their responsibilities as active members of democratic communities. For Dewey, neither aspect of this tension was optional.

Experiential education also finds its roots in the work of Kurt Hahn (the founder of Outward Bound) and Freire, because these educators were focused on developing the capacity of individuals to take action for participation in a democratic society. Freire, a Brazilian educator from the critical tradition, gave primary emphasis to praxis—the dialectal process of reflection informed by action and action informed by reflection. Inspired by the German American psychologist Lewin, Kolb adapted a Deweyian model to conceptualize experiential learning as a staged, cyclical process (see Figure 1), which ran as follows: A person engages in a *concrete experience*, and then reflects on this (*reflection*), makes generalizations

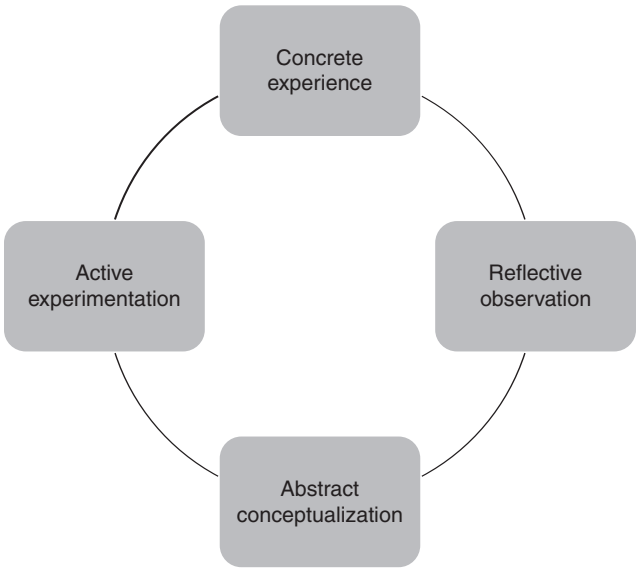

Figure 1 A Simplified Version of David Kolb's Experiential Learning Cycle

Source: Adapted from Kolb (1984).

from the reflections (*abstract conceptualizations*), and then thinks about how he or she might act differently next time (*active experimentation*), and applies these ideas to the next concrete experience.

Since the development of Kolb's model, many other authors have used different labels to describe the steps or introduced some additional steps, but the basic principles have remained unchanged. Kolb also used the stages in his model to describe different learning styles and ways of understanding or knowing things, but these are not pertinent to the discussion of experiential learning here. In more recent times, there has been strong criticism of the efficacy of such a cyclical model to adequately conceptualize the experiential learning process that Dewey had outlined. This along with other critiques will now be discussed.

Tara Fenwick sought to disrupt conventional notions of experiential learning in her book *Learning Through Experience: Troubling Orthodoxies and Intersecting Questions*, which was written for the adult education field. She encouraged more discussion about alternate conceptions by presenting critiques from constructivist, psychoanalytic, situative, critical cultural, and enactivist perspectives; and she explained how these different (and sometimes conflicting) perspectives provide a balanced view of the strengths and weaknesses of experiential learning. One of the key issues she raised was that some theorists and practitioners create a reflection–action (or mind–body and individual–context) binary. In practice, it is relatively easy for facilitators to avoid this binary by framing doing and reflecting as simultaneous, or overlapping, processes. Donald Schon's idea of reflection-in-action was a good example of how professionals may do this.

Fenwick also argued that traditional constructivist notions of experiential learning are simplistic and reductionist because they do not explain the role of desire in learning; they reinforce a conduit (input–output) understanding of learning; they falsely presume that subjects are divided from their environment and their experiences; they predominantly emphasize conscious, rational processes; and they assume a stable, unitary self. Fenwick encouraged practitioners to think more deeply about the processes involved in experiential learning.

More recently, Jayson Seaman has argued that stepwise experiential learning models inadequately explain the holistic nature of learning processes that are central to learning from experience and that they lack scientific and philosophical foundations. He suggested that an overreliance on cyclical experiential learning models may actually be influencing research and practice in unhelpful ways. The challenge is to make sure we do not limit our theorizing or repress both experiencing and learning processes.

Experiential learning has the potential to inform current and future pedagogies, but it is recommended that practitioners have a robust understanding of the theory and philosophy underpinning such practice to optimize learning outcomes and avoid experiences that may be miseducative. Finally, it is important to note that the teaching approaches used in experiential education are fundamentally different from those that may be suitable for traditional educational approaches. Consistent with the principles outlined by Dewey, a more facilitative teaching approach is required to allow students to become critical thinking, self-motivated, problem-solving individuals who participate actively in their communities.

Experimental and Quasi-Experimental Designs for Research: Campbell and Stanley

The American psychologists Donald T. Campbell (1916–1996) and Julian C. Stanley (1918–2005) are widely considered pioneers in the study of educational research designs. Their work individually, together, and with colleagues has profoundly influenced the field of experimentation not only in education but also in social science research more broadly. In their 1963 monograph, *Experimental and Quasi-Experimental Designs for Generalized Causal Inference*, Campbell and Stanley provided a detailed specification of the conditions under which research studies could validly yield causal conclusions. Often referred to simply as "Campbell and Stanley," this brief but classic work stands even today as the most oft-cited source for educational research studies that employ some form of experimental design. This entry describes the monograph's methodological contribution and the Campbell and Stanley framework for research design.

Threats to Validity

Campbell and Stanley were primarily concerned with the degree to which a research study could be designed so that it would ultimately warrant the making of *valid* inferences—that is, inferences that could actually be supported by the evidence collected during the study. Campbell had previously identified two forms of such validity: (1) *internal validity*—the degree to which the outcomes observed subsequent to delivery of the intervention or treatment in fact did occur as a result of the intervention in the experiment, rather than as a result of other factors not systematically examined as part of the study; and (2) *external validity*—the degree to which the outcomes observed in the experiment at hand could generalize to individuals, settings, treatments, and measures other than those directly observed or sampled in the study.

Campbell and Stanley also identified several conditions that could reduce the likelihood that an experiment would support valid inferences—in their words, conditions that would threaten validity. These threats to validity, eight of which pertained to internal validity and four of which pertained to external validity, have provided a means for countless investigators to reduce the likelihood of carrying out the hard work of research studies only to find out afterward that evidence fails to support valid inferences.

Researchers use Campbell and Stanley's account of these threats to validity to make decisions during the research design stage to anticipate problems that could ultimately weaken the inferences that they could make; in other words, an experimental study could be designed to have features that would minimize threats that, given the prevailing circumstances, Campbell and Stanley had said were likely to occur. For example, Campbell and Stanley identify the effects of "History"—"the specific events occurring between the first and second measurement in addition to the experimental variable"—as one potential threat to internal validity (Campbell & Stanley, 1963, p. 5).

Consider an experiment crafted soon after the release of tablet (e.g., iPad) computers, to test the hypothesis that they will be an effective aid in second-language acquisition. Members of the group being studied are given iPads to use at school. But if iPads become very popular very quickly during the period of several months that the study is running, in many cases, the students will live in homes that purchase them; and as a result, the effect of the iPad use in class may be influenced by their access to the tablet computer at home, which the study is not designed to assess. This would represent a "history" threat—gains or losses in improved language performance might be attributed invalidly to the experimental treatment being a success or a failure whereas the results also are due to the events—the history of tablet computer use—taking place in the surrounding environment.

Campbell and Stanley laid out their full list of threats to validity as follows:

Threats to Internal Validity

1. *History*, the specific events occurring between the first and second measurement in addition to the experimental variable
2. *Maturation*, processes within the respondents operating as a function of the passage of time per se (not specific to the particular events), including growing older, growing hungrier, growing more tired, and so on
3. *Testing*, the effects of taking a test on the scores of a second testing

4. *Instrumentation*, in which changes in the calibration of a measuring instrument or changes in the observers or scorers used may produce changes in the obtained measurements
5. *Statistical regression*, operating where groups have been selected on the basis of their extreme scores
6. Biases resulting in differential *selection* of respondents for the comparison groups
7. *Experimental mortality*, or differential loss of respondents from the comparison groups
8. *Selection–maturation interaction*, and so on, which in certain of the multiple-group quasi-experimental designs . . . is confounded with, that is, might be mistaken for, the effect of the experimental variable

Threats to External Validity

9. The *reactive or interaction effect of testing*, in which a pretest might increase or decrease the respondent's sensitivity or responsiveness to the experimental variable and thus make the results obtained for a pretested population unrepresentative of the effects of the experimental variable for the unpretested universe from which the experimental respondents were selected
10. The interaction effects of selection biases and the experimental variable
11. *Reactive effects of experimental arrangements*, which would preclude generalization about the effect of the experimental variable on persons being exposed to it in nonexperimental settings
12. *Multiple-treatment interference*, likely to occur whenever multiple treatments are applied to the same respondents, because the effects of prior treatments are not usually erasable

Strategies for Mitigating Threats to Validity

Campbell and Stanley advocated three major strategies for mitigating validity threats. The first of these is use of a *control group*—an additional group selected by random assignment at the same time that the experimental group is formed; the control is treated in a similar way as possible to the treatment group except that it does not receive the treatment. (Use of a control group would have helped researchers deal with the "history threat to validity" described in the iPad example; students in both the treatment and control groups would be influenced by the historical events, allowing the researchers to take this effect into account when assessing their results, for only the experimental group used the iPads in second-language class.)

The second strategy was *randomization*, or random assignment of subjects to treatment/control groups. Random assignment leaves to chance the likelihood of systematic differences between groups (such as would constitute a *selection* threat). Finally, Campbell and Stanley also advocated use of a *pretest*, a measure of the target outcome that is administered before any experimental treatments have been carried out. A pretest helps determine whether groups were systematically different prior to the beginning of the study, which is especially important when randomization is not possible as part of a study. Another benefit of pretesting is the acquisition of knowledge about each subject prior to the study; when there is subject attrition prior to completion of the study, a pretest can give insight into the presence of an experimental mortality threat, for example.

Designs for Social Science Research

Campbell and Stanley were champions of the kinds of experiments first laid out in the 1920s and 1930s by Ronald Fisher. These experimental methods called for treatment conditions that were controlled enough to enable isolation of the effects of any individual treatment variable. They recognized, however, that educational research contexts often prohibit the sort of tight experimental control and manipulation of the methods described by Fisher. As such, though "true" experiments remained their first choice, they provided a typology of educational research studies that varied in the degree to which they would control for threats to validity. The four types of research designs identified by Campbell and Stanley are as follows:

- *Preexperimental designs*, which do not utilize adequate control groups and/or do not randomly assign subjects to treatment groups
- *True experimental designs*, which include at least one control group and employ random assignment of subjects to groups
- *Quasi-experimental designs*, which do not include random assignment but do employ an appropriate control group and gather evidence on the equivalence of that control group to the experimental group (e.g., through pretest measures)

- *Ex-post facto designs*, which explore relationships between variables but do not involve any degree of experimental manipulation

Across their four types of research designs, Campbell and Stanley also specified 16 prototypical research designs that varied in the use of the three strategies for mitigating validity threats described above (e.g., the "Pretest–Posttest Control Group" true experimental design).

Impact of Campbell and Stanley

For more than half a century, Campbell and Stanley's work has been helping researchers optimize their studies to mitigate threats to validity to the greatest extent possible, even in cases for which random assignment to equivalent groups is not feasible. Their legacy includes spawning a whole new field of modern techniques for causal inference using quasi-experimental designs. Their original work (updated in 2002 in a volume, the lead author of which was William Shadish), remains the definitive source for students and scholars of design of educational research studies. It needs to be noted, however, that during this same time period, there has been growing interest among some in the research community in the determination of causes using nonexperimental, qualitative methods, such as observational techniques. One tongue-in-the-cheek paper in a medical research journal pointed out that—despite the lack of experimental studies involving random assignment to the treatment and control groups—we know that parachutes are causally effective in preventing injury in individuals who are "gravitationally challenged" (Smith & Pell, 2003)!

Faculty Psychology and Mental Discipline

Faculty psychology is the name given to an array of related theories about how the mind functions. These theories emerged in the Enlightenment philosophy of the 17th and 18th centuries and remained prevalent in theological and philosophical discourse and also educational practice throughout the 19th century. Theories of mental faculties sought to categorize the functions of mind and explain how these faculties were related to each other and how mental faculties made sense of the outside world. It is important to note, however, that the term *faculty psychology* only came into common usage in the early 20th century as scholars in the nascent discipline of psychology critiqued the theories of mind previously set forth by natural philosophers. This entry discusses how the terms *faculty* and *mental discipline* were used to describe how the mind works, how understanding occurs, and how these terms correspond to current ideas in psychology about mental functions.

In the 17th century, a faculty was understood as a mental ability or a mental power. John Locke's (1694) *Essay Concerning Human Understanding* was the most thorough discussion of mental faculties of that era. The question Locke was trying to answer was how we come to understand the world around us. While there are objects in the world such as chairs or horses, the mind possesses ideas about these objects. How do we form these ideas? Locke's approach to this question was to consider the faculties required to form ideas. According to Locke, to form a simple idea about an observed object, the mind utilized a number of faculties. These faculties included a faculty of perception that formed an awareness of the impression received by the senses, a faculty of retention and memory that connected the new perception to earlier related perceptions, and a faculty of judgment that discerned diverse impressions of an object (say, from different angles or under different light conditions) and connected these diverse impressions with the same idea of what that object was.

Over the course of the 17th, 18th, and 19th centuries, the categorization of faculties varied among different scholars. However, certain assumptions about mental faculties remained prevalent. The first was that, through reasoning and self-reflection, it was possible to categorize what these faculties were. The second was that mental faculties formed and organized ideas. The third was that the mind was an inner entity separated from the outside world. The faculties functioned to bridge the gap between mind and world, although it should be noted that explanations as to how this gap was bridged differed among philosophers (e.g., David Hume, Locke, and Immanuel Kant). The fourth was a presupposition that people were capable of reflecting on their own ideas. This presupposition precluded the need to explain how people come to self-awareness and self-reflection in the first place.

Many formulations of mental faculties, including those of Locke and Jean-Jacques Rousseau, relied on empiricism. Empiricist formulations held that

mental faculties formed ideas solely through impressions provided by our five senses along with the impressions we have of our own thinking processes. Philosophers such as Christian Wolff created a distinction between empirical psychology and rational psychology. While empirical psychology depended on impressions, rational psychology provided the reasoned principles through which different ideas could be related to each other. According to Wolff, the faculty of reason nonetheless depended on premises and axioms derived from experience. However, not all discussions of mental faculties assumed empiricism. Kant argued that some forms of knowledge, such as knowledge of adding simple numbers, can be known without prior experience.

By the 19th century, the categorization of mental abilities in terms of faculties pervaded Christian theological discourse. As formal schooling became more widespread, these conceptions permeated educational theorizing as well. Throughout the 19th century, trainee teachers were instructed on how students should apply their mental faculties to make sense of the world. Students were expected to use their mental faculties to reflect on and take control of their own thinking processes and to connect ideas through rational principles. As many leading educators of the 19th century emphasized, learning was not a case of memorizing facts, but rather of understanding the principles through which related ideas were connected.

The learning process involved construing principles through which ideas could be generalized and applied. Students required effortful attention to derive principles by connecting particular words, mathematical operations, or features of objects. The attention and effort required to make use of principles were referred to as *mental discipline*. A paradigmatic example of mental discipline was learning arithmetic. In particular, arithmetic exercises were believed to demand strict mental discipline from the student as principled arithmetical operations were applied to particular numbers. Mental discipline, however, was not restricted to arithmetic. Just as principles pervaded all branches of knowledge, mental discipline was requisite in the learning of all branches (the learning of a classical language such as Latin was another paradigmatic case). By the middle of the 19th century, student recitation was the main way to practice mental discipline. Recitation did not involve the memorization of facts and texts or learning by rote but rather demanded that the student utilize his or her mental discipline to apply principled reasoning to a particular subject in the school curriculum. Some classroom practices were based on the further assumption that the faculties could be strengthened by use, in a manner analogous to the way in which one's muscles could be developed through exercise.

With the emergence of psychology as a formal discipline in the late 19th century, many of the scientific experiments in this nascent discipline were based on assumptions of mental faculties. Some studies of mental ability, for example, studied children's ability to recognize objects and connect ideas with objects. At the same time, establishing psychology as a scientific discipline involved developing new theories of mind and demonstrating how these theories were superior to preceding theories. With the rise of behaviorism in the early 20th century, faculty psychology was dismissed—it was argued that it provided nothing more than circular explanations; for example, the faculty of judgment only can be understood as the ability to judge.

Over the past century, there have been no substantive efforts to revive faculty psychology. However, some scholars have argued that faculty psychology was not so much refuted as integrated into the discipline of psychology where functions such as perception, memory, and attention are still treated as distinct mental functions. Moreover, a central assumption inherited from faculty psychology remains prevalent in many areas of psychology; namely, that the mind resides within the body and that psychology must explain how this inner mind makes sense of the external world.

Feminist Epistemology

Feminist epistemology refers to a set of feminist theories within epistemology. Equally, it refers to a set of epistemologies within feminist theory. Both sets of theories are marked by complex and overlapping areas of agreement and disagreement. So there is no single "feminist epistemology"; there are a number of them. The entry begins by explaining what is included in the set of feminist epistemologies. It goes on to trace the emergence and development of different approaches. Then it outlines the main themes in current thinking in the area. Finally, it relates them to educational research, policy, and practice.

Feminists seek to demonstrate and dismantle the invisibility, oppression, and subordination of women; epistemology is the study of knowledge. Feminist epistemology is at the intersection of these two fields of endeavor. The orthodox Anglo-American position is that epistemology is the theory of knowledge, where knowledge is taken to be justified true belief. More generally, epistemology explores the relation between knowledge, belief, and truth. In the past 50 years, there have been sustained criticisms of this orientation by feminists and others. They broaden the scope of epistemology to include the study of what is known, what can be known, how it can be known, the knowing subject in an epistemic community, and how he/she/it contributes to the discovery, construction, or maintenance of knowledge. Significantly, these broader issues pertain to physics as much as to the social sciences and humanities (Barad, 1996).

The suggestion that epistemology can—or should—be feminist has not been universally welcomed by philosophers and theorists. Some remain outraged at the idea that feminism and gender have anything to do with epistemology, or indeed with philosophy, taking the view that these subjects address such abstract and general questions that politically partial forms of inquiry are irrelevant to them (see, e.g., Longino & Lennon, 1997; Martin, 1994, chap. 6). With reference to education theory, Siegel (2011) argues that if *epistemological diversity* refers, nonnormatively, to methodological diversity and diversity in belief within the research community, it is referring to an acceptable pluralism but is not an epistemological position; however, if it is taken to imply relativism (wherein truth is relative to a framework), it is not epistemically viable and should be rejected.

From a very different philosophical tradition, those working within a tradition critical of humanism would argue that any move to constructing an epistemology, including a feminist one, is misguided, although knowing and knowledge are discussed extensively in those critical traditions.

The relationship of feminist epistemology to standard epistemology is one of both critique and construct. It includes critiques of epistemologies that obscure the salience of gender and in doing so contribute to gender injustice; but it also constructs epistemologies that can reveal the operations of gender. Critiques of traditional gender-neutral epistemologies point up the biases and inaccuracies in knowledge that have arisen from implicit assumptions that the gender of the knowing subject and/or the subject of knowledge is irrelevant in the discovery or construction of knowledge. Moving on from critique, feminist philosophers construct epistemologies that take gender into account. They argue that feminist epistemology is productive of better knowledge that will not disadvantage women and girls.

For an epistemology to be feminist, it is both necessary and sufficient that it be capable of revealing gender *and* that it be normative with respect to gender injustice. Feminist epistemology aims to overcome injustice and so aims for better knowledge. Thus, it is not relativist, even though much feminist theory and philosophy shares in the current widespread flight from transcendence (there are procedures for rational assessment of knowledge claims). Moreover, as Longino and Lennon (1997) argue, feminist epistemologies are not necessarily (or even often) exclusively feminist—an epistemology that reveals that the operations of gender may equally reveal the operations of other material, social, or cultural formations such as social class, race, religion, culture, disability, and sexuality.

The Emergence and Development of Feminist Epistemology

Feminist epistemologies emerged during the early 1980s during a period of intense development and contestation in feminist theorizing. The different approaches developed in conversation with each other. Therefore, although they are analytically separable, they have areas of agreement as well as disagreement. A significant influence was the simultaneous emergence of political movements related to "race," ethnicity, social class, and sexuality.

Empiricism, Standpoints, and Situated Knowledge

One strand emerged from a critique of neutral, realist empiricism demonstrating that apparently neutral

empirical studies were biased, because, for example, they did not include females or assumed the universality of male experience. As a result, educational theory and practice advantaged boys and men rather than girls and women. The critique of neutrality evolved into the construction of standpoint epistemology, which held that since men as a more powerful social group understand less of the world than the less powerful social group of women, the latter perspective gives a richer, more adequate account of the world. This argument applies to other social groups as well, such as those marked by class, race, and ethnicity. So a number of different standpoint epistemologies were developed, drawing on Marxism, psychoanalysis, and postmodernism (Harding, 1986).

Other developments moved away from the notion of standpoint altogether. Rejecting the dualistic and hierarchical basis of standpoints, Haraway (1991) proposed the notion of situated knowledge, which requires engaging with "many kinds of heterogeneous accounts of the world" (p. 199). Drawing on Michel Foucault to theorize Black feminism, Collins (1991) used the term *subjugated knowledges*. Stanley has used the same term in her critiques of standpoint epistemology, in which she proposed an epistemology of the material that takes into account differences in the experience of material reality, highlighting circumstances, especially those productive of silencing and of subjugated knowledge. Narrative and autobiography/biography have been significant in all of these theories; they blur the subject and object distinctions, closely connecting the knower and the known. Code (1991) argued that the role of the social illuminates the inescapability of responsibility in epistemology. Some theorists continued to emphasize the primacy of gender as a category. Belenky, Clinchy, Goldberger, and Tarule (1986) argued that there are ways of knowing that are specifically female, which have been neglected and disparaged. The argument has been widely criticized for its essentialism and because, it is argued, the phrase "ways of knowing" is misleading and refers to ontology and metaphysics rather than to epistemology. Code (1991) argued that gender is always "a determining ingredient" in how far women's knowledge is accepted as trustworthy and authoritative.

Reason and Rationality

A second strand of critique focused on reason and discussed ways in which its apparent neutrality hid its gendering. Lloyd (1984) not only traced changes in the concept of reason over the centuries but also noted that it has always been defined by excluding the feminine, from the Pythagorean table of opposites to Immanuel Kant, G. W. F. Hegel, and Jean-Paul Sartre. Irigaray (1985) noted the same binaries at work but argued against exclusionary models, drawing on psychoanalytic and phenomenological concepts of the imaginary to argue that rationality in Western thought is conceptualized as male. Le Doeuff (1989) examined the discourse of philosophy analyzing the "domain of the image" in the philosophical writing of Plato, René Descartes, Kant, Jean-Jacques Rousseau, and Arthur Schopenhauer, among others, to demonstrate the gendering of reason in their work.

Braidotti (1991) argued against the project of constructing a feminist epistemology. She argued that Western philosophy is so imbued with a particular conception of reason, exclusive of women, that feminist attempts to reconstruct it were attempting to do no more than reform orthodox epistemology. Appreciative of Irigaray's project of "jamming the theoretical machinery" through mimesis and deconstruction, Braidotti proposed approaching questions of knowledge through a radical, nomadic, Deleuzian approach to philosophy as creative and formative rather than analytic and reactive.

Influential Themes in Current Thinking in Feminist Epistemology

Current thinking in feminist epistemology is as energetic and various as it was in the 1970s and 1980s. It is likely that the field will continue to develop at a rapid pace; this section outlines the main themes, but it should be read not as definitive but as indicating areas for further exploration. These explorations will overlap with mainstream philosophy, especially in the fields such as social and virtue epistemologies, epistemologies of ignorance, epistemologies of resistance, actor network theory, and posthumanism.

Clear links to standpoint, situated, and subjugated knowledge can be seen in more recent developments. In some formulations, it can be seen as a specific form of social epistemology. Longino argues for an epistemology based in feminist theoretical virtues: novelty, ontological heterogeneity, mutuality of interaction, and diffusion of power, which she contrasts with traditional cognitive virtues (Longino & Lennon, 1997). In the same article, Lennon accepts this but adds the requirement to pay particular attention to marginalized knowledge in a process of "world traveling." Cavarero (2002) draws on Hannah Arendt in her proposal that an epistemology

of the unique and particular, constructed through listening to multiple histories and perspectives, is appropriate for the study of human plural interaction and contingency: the *bios politikos* rather than the *bios theoretikos*. In a related move, Code (2006) discusses the politics of epistemic location. Some problems of epistemic location are highlighted in the epistemologies of ignorance, theoretically explored by feminists and theorists from other social groups (Fricker, 2007; Tuana & Sullivan, 2006).

Feminist epistemologies include not only the political but also the ethical. There are clear links here to virtue epistemology. The role of ethics is particularly clear in the discussions of ignorance and "world traveling," which argue for epistemic responsibility on the part of an epistemic community and individual knowers. Ethics are also relevant in relation to testimonial injustice, which can occur when the knowledge claims by members of marginalized social groups are given little authority. Feminists also argue that hermeneutical injustice arises when power relations constrain women's ability to understand their own experience (Fricker, 2007). In general, feminist epistemologies abandon what they argue is the pretense of objective observation; instead, the affective is fully acknowledged in the relation between the knowing subject or epistemic community and the known.

Feminist epistemology is still seen as a mistaken project by some feminist philosophers who would say that a feminist epistemology is a contradiction in terms, at best a strategic move toward dismantling the whole notion (Code, 1991)—or even just irrelevant (Tronto, 1993). From a poststructuralist and postmodern perspective, the imbrication of knowledge and power means that the humanist project of epistemology needs to be abandoned altogether, not merely reformed. Gatens (2000), like Braidotti, argues for the continuing significance of keeping gender visible while continuing to be skeptical about epistemology and what they argue are its foundational dichotomies, such as nature/culture. Drawing on Baruch Spinoza and Gilles Deleuze, they take a posthumanist turn to discuss knowledge rather than a theory of knowledge. Posthumanism is also significant in the work of Code (2006) and Barad (1996).

Relevance to Educational Research, Policy, and Practice

Feminist epistemology is relevant to educational research, policy, and practice. Suggestions about how it is relevant depend on the particular epistemology (or epistemologies) that is (are) espoused. Many of these are not uniquely feminist in the sense defined earlier in this entry. Moreover, since the field is fast-moving, scholars will, no doubt, find specific areas where it is particularly significant. Or, since there is plenty of controversy about whether any version (or none) should be espoused, some scholars may find they need to mount a defense or attack from new angles.

Educational research is one area that has long recognized claims for the significance of feminist epistemology, whether or not those claims have been upheld although these claims have not always been upheld. Particularly relevant in recent work are questions of the relation of the knowing subject or epistemic community to the known; narrative, plurality, and particularity; testimonial and hermeneutical injustice; and posthuman issues of agency. Epistemologies of ignorance point the way to new research areas and possibly to new methods (Code, Phillips, Ruitenberg, Siegel, & Stone, 2011).

Educational policy and practice are concerned with knowledge and ethics, so close attention ought to be paid to the epistemologies of ignorance and the importance of epistemological responsibility. Implications are clear, for instance, in areas of curriculum design and pedagogy. The concepts of world traveling, testimonial injustice, hermeneutic injustice, and cognitive authority are all significant in decisions about what to teach and how to do it. Although there is still little published theory and philosophy in relation to these areas, there is increasing interest.

Feminist Ethics

Feminist ethics aims to counter the traditional exclusion of women from participating in establishing the underlying assumptions, judgments, and emphases in the field of ethics. Women have not had a significant voice in discussing and questioning the presuppositions about who should make ethical decisions, about the kinds of reflection ethics should favor, or of the range of issues that can be considered to have ethical significance. This entry first describes the emergence of feminist ethics as a critical response to traditional masculine ethics and explores a selection of the diverse expressions of feminist ethics. It then considers how feminist ethics has influenced educational theory and practice, with reference to equality in education, curriculum and pedagogy, moral and citizenship education, relationships between school and family, and school ethos and leadership. Finally, it raises some ongoing critical disputes about and within feminist ethics.

Origins and Approaches to Ethics

Feminist ethics challenges a long history of doubt about whether women could reflect on and make decisions about ethical matters at all. From the 1980s, it emerged into the mainstream of philosophy, in line with growing academic attention to gender matters in various fields including education. Although traditional assumptions and issues in the history of ethics had been questioned by Mary Wollstonecraft, John Stuart Mill, and Simone de Beauvoir in the 18th, 19th, and 20th centuries, respectively, significant progress in establishing feminist ethics as a recognized endeavor became possible only in the wake of the activism of the women's liberation movement in the 1960s and 1970s. Feminist activists protested and resisted discrimination against women in the workplace and the home, raising issues that became worthy of academic attention; and feminist theory, especially in sociology and philosophy, started to address problems hitherto omitted from the ethics agenda. Feminist ethics changed the previously constituted focus of ethical theory by vociferously critiquing women's oppression and inequality and their assumed inferiority, challenging the conceptual bifurcation of public and private, and taking on aspects of social policy such as violence, sexuality, law and the family, employment and labor law, and women's agency,

development, health, and welfare. Not only had the experiences and concerns of women largely been ignored, but it also had been assumed that women lacked the necessary capacity—psychological and cognitive—for ethical reflection. Different virtues were expected of them: obedience, submissiveness, modesty, and caring.

The new feminist ethical engagements had implications not only for women but for all marginalized groups. Feminist ethics also differed in style from the traditionally argued texts of mainstream ethics, drawing in more wide-ranging forms of discourse including the novel, poetry, and autobiography. Criticizing the preoccupation of traditional ethics in the dominant Kantian tradition, with its rationally derived, supposedly disinterested judgments by autonomous individuals, feminist ethicists objected to the assumption that the ethical subject was a reasoning male who engaged in reflection about principles to be universally and impartially applied.

Challenging what feminists identified as masculine values and the exclusion of the body, emotions, and, particularity, key features of feminist ethics fall into four overlapping categories. First, it rejects the underlying assumptions and central concepts of traditional Western ethics that had ignored women's experience and reflected a profound gender bias. Second, feminist ethics rejects the subordination of women and is determined to foster their agency as well as gender equity. Third, it develops an alternative perspective in ethical theory that is informed by a revised conception of personhood. Fourth, it offers a feminist treatment of a different set of key ethical issues, realized by an expanded set of conceptual tools more suited to the task of ethical reflection and choice.

Yet in marking out these key differences, feminist theorists have adopted diverse approaches. For Marxist feminists, the central problem is the class system, in which women's domestic labor is exploited in the reproduction of children and also in ensuring the availability of men's labor outside the home. The priority for lesbian feminist ethics is resistance to oppression and domination, taking as paradigmatic caring relations among lesbians rather than between mother and child; in these relationships, there is reluctance to impose one's own conception of the good on others, and ethical choices are made in a shared context of resisting domination. From the perspective of radical feminist ethics, women need to take control of their own desires and reproductive powers, resisting compulsory heterosexuality. Stressing the need to de-essentialize, poststructural feminists critique the binary categories of gender and sex, arguing that we can only begin to understand the oppression of women by appreciating multiple explanations and the fluid social and cultural constructions of sex, gender, and sexuality. Emphasizing power, discursive constructions, and the necessary impermanence of understandings, some poststructural feminists see identity and gender as performances that change over time and under different circumstances. At least implicitly, all feminist ethicists raise key questions around gender as a social construct versus sex differences as innate and natural.

Justice and Care

A defining development in feminist ethics has been its critique of John Rawls's theory of social justice, the authoritative 20th-century work in liberal, ethical, and political theory. His theory describes basic features of a just society and the principles that regulate the lives and opportunities of its members, the distribution of goods and positions of power, and the terms of cooperation. Rawls proposes liberal principles that would be endorsed by free, equal, and rational persons: moral equality, respect for individual rights, and a fair distribution of both the burdens and the benefits of social and economic goods. The device of the hypothetical veil of ignorance famously presents his procedure for arriving at fair principles of justice by positing a thought experiment that involves blocking off knowledge about personal factors such as one's abilities and economic position. Participants in an imagined "original position" do not know what social role they would be occupying nor what interests and talents they would have (or lack) and so, presumably, would not support unfair social arrangements when deliberating about the nature of a just society. This procedure, Rawls posits, would lead to two principles of justice being accepted: (1) equal liberty for all and (2) fair equality of opportunity, with inequalities permitted only if these were for the benefit of all citizens.

Standard feminist criticisms of Rawls's ethics, and of the European Enlightenment tradition he is seen to represent, question the emphasis on reason, autonomy, and the independent individual as a bearer of rights who is devising and applying just principles impartially to all. Critics have been quick to point out that far from being equal, free, and independent, real ethical subjects are social beings

who are defined by interdependence with others and who are dependent for significant parts of their lives on the care of others. As an alternative to an ethics of justice, the feminist ethics of care places particular value on caring relations. Drawing frequently on the example of care between mothers and children, an ethics of care will be premised on trust, responsiveness to needs, cooperation, and reciprocity and will include attention to the role of emotions in understanding moral issues and moral decisions.

Critical of the abstract universalist emphasis on the rational individual, the moral psychologist Carol Gilligan offered one such alternative moral theory, claiming that men and women speak from and are driven by different moral standpoints, namely, the justice and the care perspectives, respectively. While keen to resist the assumption that the voice of care is, necessarily, the voice of women, Gilligan's work nonetheless suggests the existence of gendered difference, ascribing more connected, relational, caring roles to girls and more justice-oriented roles for boys. The moral development of boys will be more rational, more logical, and focused on making decisions on the basis of principles of justice, while girls will more likely attend to relational thinking and care, mirroring relationships with their mothers. Although her work remains controversial for many feminists, including those concerned that most of her subjects were White and middle class, Gilligan's contribution to the development of feminist ethics was significant: No longer could girls and women be omitted from developmental and moral psychology. Importantly, too, Gilligan encouraged a much greater focus on caring, for both men and women.

While a number of feminists regard caring as an ethical issue, Nel Noddings, arguably the best-known care ethicist among educators, insists that care and justice are distinct. Noddings's relational theory of care is premised on paired relationships in which care is at best natural, with "ethical caring" occurring only when a carer feels obliged to offer care. Clear that her theory of care, influenced by Gilligan's work, is neither comprehensive nor universal, Noddings holds moral decisions to be partial and located predominantly in the private domain with moral principles unnecessary. For some feminist ethicists, this raises the question of how we are to ensure that care is morally appropriate and that our circles of concern can transcend the immediate and partial. With respect to some accounts of care, feminist critics have also asked how women are to avoid the stereotypical trap of assuming the bulk of the responsibility for care in both the private and more public spheres of work. Care, wherever it occurs, is arguably an ethical issue demanding moral appropriateness and decisions based on a conception of the social good resulting in care that is both implicated in and can realize justice, and in care that is less gendered, less often the prerogative of women.

In education today, women are still often expected to be responsible for care and nurture. In the early years of schooling especially, women may take on roles more akin to traditional "mothering" than those most obviously attributed to educators. Do women accept such roles simply because they have, for the most part, been mothered, or because they are "naturally" predisposed toward nurturing, empathetic, close relationships, as the work of some early care theorists might suggest? On some accounts, women reproduce the caring they have received, understanding and "feeling" the needs of others, while men are more likely to see themselves as different and separate from their mothers and their "feminine" behaviors and capacities. On such views, the reproducing of motherhood might sustain the hegemony in which women are oppressed by expectations that they will assume caring roles while men are free to pursue careers. Accordingly, the ethics of care has been the subject of critique from feminists determined to counter understandings of care that can trap women into self-sacrificing disregard of their own interests and open them to exploitation and even abuse as the needs of others are given priority.

Feminist Ethics in Education

Feminist ethics in education pays particular attention to equal access to education through the just distribution of resources and to participation in historically male-dominated subjects like science, and it offers a critique of gendered curricula, including the hidden curriculum. With respect to moral education and citizenship, regardless of sex, it holds that citizens are to engage in rational deliberation between competing claims and opinions, are to be caring and are to be allowed a voice. The ethics of care has been extended to relations with others beyond the immediate and intimate, to the environment, and to distant others.

In a world now connected by neoliberal globalization in an integrated economy that favors the interests of the rich and powerful, the poorer underdeveloped regions are now locked into postcolonial

dependency. Global justice requires redistribution of goods and agency and that the less powerful who are excluded from making decisions with global consequences be given a voice. Some proponents of the ethics of care would observe that a justice-based ethics is not enough to prompt action to address global inequality and Third World poverty and that the ethics of care must be extended to distant others. If citizenship ethics is now informed by a notion of global citizenship, the extension of feminist ethics to the global context further illustrates how both care and justice have a part to play in recasting all ethical domains. Both care and justice offer instructive means for feminists to address contemporary ethical challenges in which there might be a shift from power relations between sovereign states and their citizens, often executed by war in what feminist critics of traditional international relations would interpret as a masculine intervention of the state and its citizens in competition with other nation-states.

School and Family

In liberal feminist ethics, the home is a legitimate focus of critique. While Rawls treats the home as the first school of moral education, what children learn in this school became a focus of feminist critique, as did Rawls's assumption that the "head" of the family would be a man. Feminist ethicists question the often inequitable domestic division of labor and the "natural," frequently implicit, authority of men over women in the family. Contrary to assertions that the family must necessarily be a good, healthy, and just institution, feminists have pointed to the family as being a site where both the reproduction of gendered inequalities across generations occurs, and where sex-based abuse—physical and psychological—may occur largely unnoticed. Feminist ethicists point out that attention to the family and calls for a return to "family values" frequently fail to attend to the diversity of the family today. There is also ongoing controversy about whether cultural practices regarding early or arranged marriage should be respected or whether critical thinking taught in the school should extend to such matters in liberal democracies. While Noddings extends care ethics from the home to public policy, other feminist ethicists see a role for the state in establishing the legal definition of the family and associated rights and responsibilities, and some feminists advocate a stronger role for schools in "undoing" the gendered assumptions and attitudes that may have been fostered in families.

School Ethos and Leadership

The tendency for men to dominate in positions of leadership in educational institutions is a further issue of concern for feminist ethics, not least with respect to ways in which such domination perpetuates a deeply gendered organizational culture and ethos in which women are relegated to lower echelons of the teaching profession. There appears to be a continuing assumption that while women are effective in subordinate roles, especially caring for young children, they may be less suited to and lack the necessary attributes for leadership. If, for whatever reason, women do have different ways of being and doing, the ethos and organization of schools might change for the better if they could both reflect and capitalize on women's talents. Leadership more effectively directed toward values central to feminist ethics might result in greater attention to things such as caring, relationships, more inclusive and democratic practices, and emancipation for staff. Feminist ethics offers resources for critiquing leadership practices and their effects on the ethos of the school while also providing the tools for subverting neoliberal policies and their resultant pressures on curriculum and pedagogy.

Feminist Pedagogy

Feminist pedagogy offers further opportunities to realize schools that can be both more caring and more powerful sites of struggle against the reproduction of hegemonic gendered practices. Curricula, on a feminist approach, will attend to issues of oppression and injustice across all sectors of society, including those affecting all women, while feminist pedagogy will disrupt the gendered status quo by revealing and disturbing traditional power structures and practices. It will give voice and autonomy to girls and women, thereby opening up opportunities for learning and for careers that are gender neutral, based not on one's sex but on what one is able to do and to be.

Current Controversies

Nature Versus Nurture?

Recent research in neuroscience on sex similarities and differences has reignited the controversy over the importance of nature versus nurture, and feminist ethicists have warned of the dangers of what has been termed *neurosexism*. They emphasize that the plasticity of the brain and its capacity

to respond to the environment is perhaps more important than ever, if feminists are to avoid a new master narrative of essentialism and, from whatever ethical perspective, to resist a return to a deterministic acceptance of gendered difference. Cordelia Fine has identified issues in the research itself and examined implications for educational policy and practice.

Justice Versus Care?

While some might assume that care and justice are mutually exclusive orientations, the range of ethical issues that feminists have identified in education can fruitfully draw on both. Liberal feminism has taken plausible steps to adjust the ethics of justice to accommodate the feminist critique of its traditional and Rawlsian expressions. So, for example, Martha Nussbaum's "capabilities approach" attends to both justice and care, building from—but critical of—some key elements of Rawls's account of justice. She is uneasy with the basic goods that Rawls identifies for just distribution, such as income, wealth, and position in society. She also finds that the free and equal parties in Rawls's original position do not take human diversity sufficiently into account, proffering instead a conception of persons that acknowledges that they are dependent on the care of others for at least part of their life span. Her account of social justice supports strategies to change institutions, including the family, to address women's place and the comprehensive doctrines that underpin the traditional views. She is critical of any approach to feminist ethics that supports, even implicitly, uneven power relationships such as one might witness in the family. Women should be treated as individuals of equal value and dignity, whatever their circumstances. Thus, Nussbaum's capabilities approach is focused on what all people are able to do and to be. A list of 10 central capabilities represents Nussbaum's response to questions about what is required to enable all to live a life with dignity. Importantly, Nussbaum's capabilities approach is premised on a construct of personhood in which all people are ends not means, and according to which, women may not be treated as means to the ends, to the plans and goals, of others. Such an approach has obvious implications for the equity of women's opportunities and their roles, duties, rights, and entitlements in social institutions such as families, schools, and places of employment. Nussbaum insists that it is unjust for women to be primary caregivers if providing care deprives them of any of the 10 central capabilities; it is the role of a good society to provide care for those who need it without exploiting women.

Feminist Ethics: A Colonial Discourse?

Like feminist theory in general, feminist ethics is vulnerable to the criticism that it is written mainly by Western, White, middle-class academics who succumb to precisely what they object to in traditional male-dominated ethics. Indulging unwittingly in race, class, and cultural bias, they mistakenly impose their own experiences and assumptions on working-class, Black and Chicana, aboriginal, Muslim, and other women in developing countries. Their critique of cultural practices in dress and in sexual and marital practices that they see as oppressive depicts women in these societies as voiceless, uneducated victims controlled by their men and in need of emancipation from tradition. Such alleged hypocrisy is compounded, moreover, by the material benefits that Western women derive from a global economy that has been especially destructive for Third World women's livelihoods and agency.

This critique of mainstream feminist ethics insists that the voices of women outside Europe and North America be recognized. These women have a principled and strategic need to develop an ethical discourse in their own context, safe from critique from outside hegemonies. Western feminists should avoid the temptation to speak on behalf of other women, failing to hear their voices. Instead, they need to attend to finding nonpatronizing ways to learn from them, in a manner that is inclusive, equal, and respectful.

Globalization in an integrated world economy has brought women from materially privileged and from developing countries into forms of association that demand an ethical response. Third World debt, unfair rules of international trade, and vast inequalities in access to educational opportunities help maintain the competitive dominance of the most developed economies. There is a danger of not acting on global injustices consequent on colonialism and neocolonialism for fear of inadvertently speaking on behalf of others. Insulating closed communities from all forms of critique may protect local patriarchies as well as global capital. Moreover, it might even discourage dissent from women in developing countries, who should not be treated as members of closed epistemic and ethical communities incapable

of engagement across difference. The terms of such engagement and possibilities for a global feminist ethics are still under negotiation.

Feminist Standpoint Theory

Feminist standpoint theory emphasizes that women and men typically have different social positions and experiences. Women are, by and large, underprivileged relative to men and experience reality through work in ways men often do not. This can give women an epistemic advantage; they can know some things in a better or deeper way than men can. The advantage is potential and has to be realized through learning or consciousness-raising groups where women meet to discuss their experiences. This has important implications for education. Significant epistemic differences (grounded in significant social differences) call for different methods of learning. Women should be educated in ways suited to their potential that allow it to be realized as advantaged knowledge. Furthermore, as emphasized by Sandra Harding, standpoint theory implies that we should focus on the experiences of women and other underprivileged or marginalized groups as a source of knowledge and understanding; there is much to learn from them. This entry follows the development of feminist standpoint theory and explains its main characteristics and the criticism raised against it in feminist scholarship.

Early accounts of feminist standpoint theory (e.g., Dorothy Smith's and Nancy Hartsock's) were pronouncedly influenced by Marxist accounts, according to which the working class has the potential to understand the social and economic reality more reliably than does the exploiting bourgeoisie. The bourgeoisie's interest in suppressing the truth about how it exploits workers hinders its ability to conceive the social reality as it truly is. The working class, in contrast, has an interest to see the exploitative social reality for what it is so that it can be brought to an end. Moreover, the working class has greater potential to conceive the social reality accurately because it experiences firsthand its dire aspects. The working class is epistemically advantaged also through its potential to develop a "dual vision": Because of the dominance of the bourgeoisie, its ideology is known also by the working class, which, therefore, is familiar with both its own and the bourgeois understandings of reality. The bourgeoisie, however, has access only to its own point of view. But workers have only the *potential* to enjoy their epistemic advantage. Many suffer from false consciousness as they internalize the bourgeois ideology and values and, thus, do not comprehend their exploitation for what it is but deem it deserved and just. Advantaged knowledge often has to be attained through education and effort.

Feminist standpoint theory, especially in its earlier stages, drew largely from this model but replaced the Marxist class division with a feminist gendered division of labor. Like the working class, women experience many of the material aspects of the world. Women do so through housework and child rearing, in ways that men do not. Women have

the motivation to notice the unjust sexism in the social reality that men have an interest to ignore. And women, too, have the dual vision (which early feminist discourse sometimes called "bifurcated consciousness") of both their own and men's conceptions of reality. As in Marxist theory, in feminist standpoint theory as well, mere group membership is insufficient for enjoying the advantage. Since many women suffer from false consciousness that leads them to accept their underprivileged condition as good and just, attaining advantaged knowledge requires education.

Marxist thought considers the relation between the working class and the bourgeoisie as the most basic and important one in the modern era. It downplays the other types of oppression from which workers suffer (e.g., national, racial, or colonialist oppression) and takes the latter to be less significant or largely based on the primary one. Similarly, early feminist standpoint theory focused on women's oppression as a basic phenomenon and tended to downplay other types of oppression from which women suffer or to see them as mere variations on women's oppression. Later feminist standpoint theories, however, have emphasized also these other types of oppression. Patricia Hill Collins, for example, has argued that Black women's experiences and White women's experiences differ in important ways and, thus, that Black and White feminists have significantly different standpoints. Collins's analysis implies that the differences between White and Black standpoints may be as important as those between women's and men's standpoints. In some ways, Black women and men may have more in common than Black and White women. This, of course, has been claimed also for other underprivileged groups. It has been suggested that several axes of oppression can intersect in every person. A person may be oppressed in some ways (e.g., as a woman) while an oppressor in others (e.g., as a wealthy, Western White person). Thus, standpoints have come to be understood as complex, encompassing many social positions that may inform one's epistemic positions in a variety of ways.

It has been argued that such analyses develop feminist standpoint theory in some ways but undermine it in others. These analyses suggest that there are many types of oppression and that women's oppression is no more important than others (e.g., oppression of Blacks, Hispanics, or the poor). But this runs counter to the notion that there is a relatively united, homogeneous women's perspective, with only some minor variations (between, say, White, Black, Hispanic, and poor feminists). Thus, under these analyses, women's standpoint emerges as highly fragmented, to the extent that it is no longer clear that it makes any sense to talk of women's standpoint at all or to see it as a focal standpoint that enables advantaged knowledge of many issues, as the working-class's standpoint is considered in Marxist theory. Indeed, many postmodernist feminists have completely rejected the notion of a feminist standpoint, emphasizing, instead, myriad changing positions in each person. To cope with this problem, feminist standpoint theorists have had to argue that women's oppression is somehow more important or severe than other oppressions. But many feminist standpoint theorists have been reluctant to make this move, while many Black, Hispanic, and other feminists are unambiguous in their rejection of it.

Some feminist authors have voiced other criticisms of feminist standpoint theory. Bat-Ami Bar On, for example, has argued that since the theory found women's epistemic advantage on their oppression, it forces women to choose between continuing to have accurate knowledge and ending their oppression. Sylvia Walby has claimed that founding epistemic perspectives on different social economic positions raises questions about the possibility of sharing knowledge. The more people's knowledge is taken to be based on their different economic and social positions (rather than, say, on interaction or education), the more unclear it is how people succeed in sharing or communicating knowledge. Yet knowledge is frequently and successfully shared and communicated.

Another line of criticism acknowledges that women's experiences in childbearing, child rearing, housework, and certain other activities may endow them with advantaged knowledge in these specific spheres. Likewise, women's oppression may allow them a deeper understanding of sexism in society and of other types of oppression. But critics suggest that it is problematic to extrapolate from an epistemic advantage as regards these specific issues to an epistemic advantage as regards other issues or an epistemic advantage at large. Yet another criticism emphasizes false consciousness. Many—perhaps most—oppressed women in the world endorse sexist views, such as that wives should obey their husbands or that immodestly dressed women "deserve" to be raped. Uprooting such views has proven to be very difficult and raises the question of

whether the oppressed position is not epistemically disadvantageous rather than advantageous.

Sandra Harding, probably the most prolific writer on feminist standpoint, has described it as the most controversial feminist epistemological view. Indeed, it has been criticized more than any other feminist epistemological theory. Many feminist theorists, however, still espouse it, presenting, over time, and under pressure of criticism, progressively more moderate and, thus, also more defensible versions of the theory. These newer accounts have significantly distanced themselves from their Marxist roots (which often remain unmentioned) and present the feminist standpoint as less unified and central and as endowing more modest epistemic advantages than earlier theories held. Critics suggest that these modified versions of standpoint theory are less vulnerable to criticism than their more radical predecessors but, at the same time, render the standpoint less significant and of fewer practical and educational implications.

Foucault, Michel

Michel Foucault (1926–1984) is among the most widely cited 20th-century theorists in educational research. His most important contribution to this field has been in providing the resources for a sustained critique of the educational endeavor. Due to the scope of his work—which extends well beyond educational matters—and the radical consequences of his critical perspective, Foucault's ideas are typically difficult to apply. To fully appreciate the insights Foucault has to offer, it is important to situate this work within his wider critique of the present.

Tone and Scope

Discipline and Punish, one of Foucault's most famous books, contains a statement that indicates the tone and scope of his critical venture: With the rise of modernity, according to Foucault, the soul became the prison of the body. This modern soul has no vital or inextinguishable essence, but it is no illusion either. Unlike the soul of Christian theology, it was not born in sin but was born from methods of punishment, supervision, and constraint. It was a material product created through multiple techniques, extending across sites including the newly developed institutions of mass education.

The consequence of this claim is to make freedom—a political project based on securing and protecting individual selves from the effects of dominant power—inherently problematic. For Foucault, the modern men, women, and children that 19th-century campaigners, politicians, and bureaucrats would seek to free, were already conditioned by forces much greater than themselves as the instruments of a wider political economy. Their souls, made from the resources of the institutions that had schooled them, were already limited constructs, devised to suit the needs of government in the form of responsible and docile subjects. This, Foucault argues, is the dark underside of Western modernity, which through its commitments to liberalism and democracy would secure education and votes for all. Those newly established liberties were underwritten by multiple techniques that would instruct citizens to use their freedoms "appropriately."

These are monumental claims. Many other similarly iconoclastic statements may be found in Foucault's work, which ranges from histories of madness, medicine, and prisons, to the workings of power, knowledge, government, and subjectivity. Foucault was, nevertheless, a meticulous and canny thinker, careful to avoid grand theories and epic claims. He preferred to look from the "bottom up," believing that dispassionate work, work that appears to view its subjects from above, or even from the outside, is impossible. This led him at times to appear noncommittal, unwilling to declare his political and philosophical allegiances. Foucault's work is often

doggedly and sometimes frustratingly descriptive, making it difficult to work out what Foucault was seeking to achieve in political terms. While his political commitments were strong—indeed Foucault was no stranger to protest, direct action, arrest, deportation, and even police brutality—Foucault has been criticized for refusing to declare what exactly he was arguing for or what values guided his work.

The reason for these refusals was Foucault's suspicion of those very values and what they were based on. In particular, he suspected that the human subject, in whose interests ethical systems are often justified, is always a local construction. There is no universal human subject of history in whose name we could speak. Foucault was able to show that many features of contemporary life are locally contingent, especially those features that we most take for granted. They have histories and thus, in principle at least, are open to change. Grander illusions, such as the presumed freedoms that modern education helped establish, are broken apart according to their histories. These "genealogies," as Foucault was known to call them, often muddy the origins of our most resplendent ideals by situating these ideals within the banal transformations of everyday conduct from which they emerged. Here, and in many other respects, Foucault aligned himself with the thinking of Friedrich Nietzsche, who argued that morality itself is just another social construct. The history of morality, like any other history, is marked by turbulence. Moral meanings change through unexpected reversals; there is no internal or developmental consistency to the history of morality. Often, the agent of change is trivial in appearance to be located in some minor adjustment or other that has taken place in personal or social conduct. For Foucault, histories are seldom grand or progressive; they are gray and turbid.

Power and Confession

In educational research, Foucault's work on power has been particularly influential. Here great care must be taken to avoid misunderstanding. Foucault emphasized the productivity of power, its generative potential. He was careful to avoid a repressive hypothesis where in education one might identify techniques as "bad" because they appear to limit the freedom of the student. Highly mechanistic devices such as examinations or tests are frequently placed in this category. It is tempting to identify the most severe of these as devices that trample the interior of the child and, therefore, conclude that they have no place in an educational context. Foucault would be more cautious (though, typically, thinking in a way that would be likely to outrage conventional understanding) in suggesting that these techniques may be central to the educational endeavor.

Educational techniques such as those developed by 19th-century schools (the first institutions of mass schooling) were able to shape individuality in such a way that those concerned were isolated from one another but open to the influence of government. Practices of division and exclusion (where the student is divided within, or divided from others) were combined with techniques that would enable the individual to turn himself or herself into a subject, techniques that would enable one to recognize externally defined traits within the self and then act on them. As a material reality, the modern soul constructed here depends on a terrain of concepts within which it can be determined. It relies on external categories ranging from more general ideas—psyche, subjectivity, personality, consciousness—to more child-specific notions: the troubled child, the child of promise, the borderline child, the resilient child, and so on. The child's interior, in other words, was the product of external ideas and systems for locating those ideas within the self, which, in turn, influenced how that self was formed. Foucault's interest was to identify the material practices through which this occurred.

In educational contexts, these material practices can be very intimate. Relations between teachers and students are sometimes close, where the latter are encouraged to confide in the former. Foucault explored these relations under the general rubric of "pastoral power," focusing in particular on confessional practices, where students may be encouraged to reveal and explore their inner thoughts and feelings. This might occur during periods of pastoral care or through a whole-class task as basic as a reflective diary, where students are asked to explore the events of a weekend just gone by. Foucault argued that the obligation to confess, to reflect openly on one's inner being, has become so deeply ingrained that we no longer see it as the effect of a power that constrains us. It seems as though the "truth" that is lodged within only needs to surface and that if it fails to do so, some sort of constraint, or inhibition, is to be blamed for holding it in place and weighing it down. It is presumed, in other words, that confession frees, while "power" forces one to remain silent. This, Foucault suggested, is the

"ruse of confession." His point was to argue that power functions in the opposite direction, instructing individuals to produce truths about themselves and rendering silence awkward. In educational contexts, students must learn to reflect on their "inner" selves using approved techniques and categories. The cumulative effect of observations like these is to raise the suspicion that educational relationships are never innocent; they are built from synthetic devices that have carefully fabricated effects. It is significant that the techniques described here are those associated with progressive education, thus indicating that no pedagogy is purely benign, that no pedagogy can claim to be above the stratagems of power. From this perspective, and taken as a whole, education becomes nothing less than a great artifice. Little that is "natural" or without consequence remains.

Theory and Strategy

Foucault was a subversive thinker who set about challenging conventions. It is often assumed, for example, that knowledge arrives once power departs. If power remains, so the argument goes, its effects may contaminate knowledge. Foucault sought to show how the two are intimately linked: The human sciences were born from observations, and these required human samples. Social groups such as children formed ideal test subjects. They were already in the required form of measurable samples, having been temporarily held captive by the school. For the past two centuries at least, as children and then as adults, we have been examined at multiple sites. This has led to an overall inversion of visibility thanks to which previously ignored, unknown, and marginalized groups as well as more general but minor phenomena have been brought to prominence. The production of knowledge once prioritized the powered elite whose biographies were the only ones worth telling. Now the minor historical actors, their traits and biographies, have been opened up to inspection. Either directly visible through forms of optical surveillance or indirectly visible by means of the data trail that is left when passing through various agencies and institutions, the individual is captured within an array of documents and becomes accessible thereby to the influence of power.

From this perspective, power cannot corrupt knowledge because knowledge is already the product of power and is tied up within its operations. The overall effect is to deny exemption to any form of knowledge or any science that claims the right to truth. Everything becomes subject to skeptical inquiry. The assumption here, which takes the form of a basic strategic–analytic choice, is to presume that everything is dangerous, for power is everywhere. This founding critical stance encourages the educational theorist to engage in a radical critique, targeting in particular those aspects of the educational endeavor that are seen as natural, or unproblematic, and have as a result been allowed to remain unchallenged.

According to its dispersal, power is never entirely located in powerful institutions. It is never totally possessed as if it could be accumulated and concentrated, as if it could be brought to one place so as to be absent elsewhere. Equally, it would be a mistake to assume that power is governed by a single organizing principle and to argue that an instance of power represents the wider interests of capital, patriarchy, or the state. These are displacements, Foucault argues, by which we evade the real question of power in all its complex detail.

The difficulty with this position is that it implies the impossibility of denouncing power from the outside, simply because power is everywhere. Here Foucault adopted the stance of a hyperactive pessimist, suggesting that critique is at its most productive when it remains alert, avoiding the temptation (and potential satisfaction) of standing back to offer a global analysis, and then condemn. Foucault suspected the global analysis of perpetuating an illusion of truth that would have damaging effects: Political action that is based on a single global diagnosis of power will almost inevitably reinvest some of the power mechanisms that are to be overthrown. Here, Foucault was particularly critical of revolutionary activities guided by a Marxist analysis of state power. He claimed that socialist states reproduced in different guises the cruelties and inequities they sought to destroy. Radical, emancipatory theory had failed to anticipate these outcomes because of its tendency to reduce the complexities of power to simplistic relations of domination and exploitation.

Against this tendency to blindness concerning power, Foucault argued for a profusion of gray, meticulous, and patiently constructed inquiries into the multiple effects and modes of functioning that power takes. Educational researchers who seek to adopt Foucault's theoretical framework are challenged to avoid passing judgment in their critique, which would be based on a normative ideal of the purpose of education. This antinormative injunction

will presumably enable researchers to interrogate educational concerns with greater caution and more critical insight.

It is worth remembering, however, that Foucault's invitation to exercise caution in analysis was not symptomatic of his preference for academic reserve. That was not his affliction. Rather, Foucault believed that a transformation in analytic techniques of the sort he promoted should be accompanied by experiments involving new forms of political conduct to which the insights gained through critique could be related. His was a radical project, sensitizing readers to the multiple effects of power and exploring the contingencies of government and subjectivity. Foucault promoted a form of intellectual labor that was never to be separated or abstracted from political praxis.

Freire, Paulo: *Pedagogy of the Oppressed* and Critical Pedagogy

Paulo Freire (1921–1997) was a Brazilian philosopher of education whose theory of education as a practice of freedom claimed that to realize their deepest possibilities as human beings, people needed to intentionally shape history and culture even as they were being shaped by that very history and culture. This historicity and the reflective action (praxis), the labor through which it becomes embodied, constitute the primordial capacities for free action. The nurturing of those capacities marks the foundational task of a humanizing or liberatory education.

Freire argued that oppression occurs when social, economic, political, and ideological structures undermine or prevent certain people or groups of people from enacting their basic human need to be free in order to shape the history and culture within which they live. Oppression thus constitutes a form of dehumanization.

Freire's theory of education aimed to counter dehumanization by structuring and making systematic what was most deeply human. His seminal book—*Pedagogy of the Oppressed* (1970)—elaborated the implications of his view of human nature, making historicity the starting point not only of understanding the essence of human beings but also of an emancipatory pedagogy. His theory and pedagogy have influenced movements for social justice on every continent, and they have affected classroom practices among educators seeking a humanistic approach to teaching and learning. Freire himself worked in a variety of geographical locations and was at one time a consultant to UNESCO (United Nations Educational, Scientific and Cultural Organization) and the World Council of Churches.

Foundations of the Theory

Theories of education illuminate the changes elicited from, or imposed on, human nature to turn that natural person into a morally, socially, and culturally ideal person. That is, some kind of education mediates between who we innately *are* and who we *should be*. Freire argued that praxis (reflective, conscious action) and historicity (people's capacity to make history and culture at the same time as history and culture make them) are the two defining features of human existence and the defining essence of being free. The ideal society for Freire is one that maximizes this essence for all people, and he argued that this entailed a just and democratic society.

The praxis and historicity at the core of human nature also set the task for education as a practice of freedom for a liberatory and humanistic education. This approach to education constitutes a form of cultural action that awakens people to the power that resides within them to transform themselves and their world. Because simply by being human we

are always already continuously producing history and culture (as history and culture also continuously act on and condition us and our world), we need only become critically and consciously engaged in that process (praxis) to be enacting our capacity to be free and to be forging a society shaped toward ends we have chosen for ourselves. In a society that is unjust and nondemocratic because large numbers of people are oppressed or dehumanized, and are excluded from participating in their own self-determination, this kind of education creates a counterforce to these realities and embodies just and democratic practices.

A liberatory education involves oppressed communities in a collective questioning of the "commonsense" everyday understanding of life and of the explanations for why the social, economic, political, and cultural realities have come to be. The critical consciousness that arises through this questioning even interrogates the process of knowing itself and the self-understandings of those who are oppressed. It seeks to uncover the ideological distortions of knowledge, so that a clearer "good sense" of reality and the self can be achieved. This knowing better of what had previously been known only from a dominant ideological perspective is not something achieved in thought alone. Rather, "conscientization" or critical consciousness is only gained through action, through praxis. Paulo Freire called this praxis *dialogue* to emphasize its communicative and meaning-making properties.

Dialogue is not mere conversation, nor a way of taking turns in discussion. Rather, dialogue is a collaborative critical investigation of what prevents oppressed people from being self-determining, from intentionally producing a culture and society that accords to all this essential human right, and this investigation is embedded within ongoing actions that challenge and overcome those situational limits. This kind of dialogue provides a way for oppressed people to "speak a true word" and emerge from the "culture of silence" that has long dehumanized them. Freire regarded the "culture of silence" not simply as the ways that the literal speech, or voice, of the oppressed is prevented from being verbalized or expressed in language. Rather, this concept references the institutional and structural marginalization of the needs and interests of oppressed groups, and therefore the response—"speaking a true word"—is not achieved in language alone but only through actions aimed at challenging and transforming the institutions and power relations of the society.

Freire's radical pedagogy was designed to elicit these transformative actions. He embedded the pedagogy within literacy projects that linked the reading and writing of words (the actual interpretation and production of linguistic signs) to the reading and writing of reality (the interpretation and production of daily life). This literacy becomes critical through investigating the defining structures and power relations that shape everyday experience and identifying transformative "limit-acts" that break the constraints of dominant institutions and ideologies.

These critical investigations and efforts to reconstruct society to make it more just and democratic enable oppressed people to "know better" the "common sense" that legitimates dehumanization. With "good sense" undergirding their emerging critical consciousness ("conscientization"), they can challenge not only the social, economic, and political structures that maintain the power of the dominant groups but also the internal psychological structures that maintain their own collusion in oppression.

Freire argued that these pedagogical tasks of intentionally producing a just and democratic society in which the oppressed can be self-determining amounted to a process of *cultural action for liberation*, and this ongoing transformation of everyday life was the way in which human freedom is realized.

A Critical Pedagogy

Educators worldwide took hold of some core elements of Freire's theory, particularly its articulation of the contrast between traditional schooling ("banking education") and education as a practice of freedom ("problem-posing education"). Freire's analysis (see *Pedagogy of the Oppressed*, chap. 2) enabled educators to fashion a critical humanizing pedagogy that could be applied in classrooms for both children and adults.

Banking education centers on the knowledge, language, goals, and interests of the teacher and of the institutional, social, economic, and political power represented in the formal structure of schools and in the authorized curriculum. The teacher actively teaches, while students passively absorb what is taught. The teacher thinks and talks, and the students listen and memorize. The teacher knows, and the students are ignorant until their minds are filled with the content that the teacher deposits in them. The teacher disciplines the students to conform to the dominant order, and the students learn to be passive and compliant. Banking education not only

objectifies and dehumanizes the students through these structures and dynamics, but it prepares them to accept their oppressed position in the larger society. Even more insidiously, banking education operates under the guise of neutrality, obscuring its commitment to the maintenance of the status quo. This reinforces the dominant ideology that blames the victims of injustice, as if the effects of the dehumanization inflicted on them by the structural inequities undergirding the institutions of society, including its schools, were their own fault.

In contrast, problem-posing education rejects the possibility of neutrality and makes explicit its own ethical and political commitments. It elicits and strengthens the subjectivity and agency of oppressed students; it recognizes them as cocreators of the history and culture in which they live. Problem-posing education is dialogical and collaborative throughout, bringing the voices, interests, and perspectives of the students into a critical engagement with their everyday social, economic, and political realities. This engagement reveals the dehumanizing limits imposed on their realities by unjust social, economic, and political institutions so that they can intentionally act to transform and overcome those limits. Problem-posing education illuminates the foundational power inherent within each person and every community to make society more just and democratic.

In problem-posing education, teachers and students learn from and teach one another. Each has knowledge, values, and skills that they bring to the pedagogical encounter. The methodology of critical pedagogy centers on the analysis of representations of everyday life that encode the institutional and structural relations that reinforce and maintain dehumanizing systems of power. These "codifications" are developed through a study of the formative concrete experiences and linguistic practices that together constitute the "thematic universe" of the learners. The codifications symbolically—through images, words, dramas, or other creative productions—represent the common experiences of the oppressed, and when they are analyzed dialogically, the oppressed can get some distance from their everyday reality to be able to read it critically.

Most people, most of the time, live submerged within the ordinary experience of their lives, seldom questioning how the social, economic, and political structures came to be the way they are, or questioning the commonsense meanings and explanations that legitimate the inequitable status quo. The analysis of the codifications brings the historical development of society into view and, thereby, also brings into view possibilities for its intentional transformation in the interests of the oppressed. A critical pedagogy links the particular concrete everyday experience of the learner with broader historical and cultural structures that condition that experience. It thereby facilitates critical understandings of the causal forces that shape not only the institutional features of society but also the very identity of the oppressed along class, race, gender, and other ideological dimensions. The critical understandings become sharpened as the oppressed become subjects in history, acting with intention to intervene in the structures and processes of daily life in order to produce alternative futures. That is, in the pedagogical process of knowing themselves and their situations at deeper and more systematic levels, the learners also discover themselves as historical subjects, as human beings capable of transforming oppression.

Thus, a critical pedagogical praxis is a form of reflective, intentional, collective action, action that enables oppressed people to resist the dehumanizing ideologies and institutional structures that limit the realization of their needs and interests. A critical pedagogy facilitates the emergence of the oppressed people's capacity to speak for themselves, to name and pursue self-determined goals, and to organize and mobilize for the assertion of their rights.

Criticisms and Limits of the Theory

Although broadly acclaimed and widely read—more than a half million copies of his foundational book, *Pedagogy of the Oppressed*, sold worldwide in its first 20 years—Freire's theory was criticized from a variety of perspectives. Some Marxists found it too Hegelian or idealistic, with too much emphasis on the communicative and cultural features of society rather than on the material conditions and relations of labor. Some feminists noted how its emphasis on socioeconomic class completely elided gender oppression, while other critics noted the elision of race oppression. Related to both of these criticisms were questions raised about the complexities due to the intersection of class, gender, and race oppressions; only very limited insight into this constellation of issues could be provided by Freire's binary analysis of oppressor–oppressed. Some scholars were concerned about the overemphasis in the theory on cognitive understandings of consciousness, with the concomitant exclusions of the body, feelings, and

emotions from the analysis not only of critical consciousness but also of both oppression and liberation. Related to these criticisms were questions raised by some thinkers who discerned a problematic reliance in the theory on European-origin philosophies, modernist logics, and cognitive forms of rationality.

These substantial criticisms have been echoed in philosophic examinations of Freire's theory, which focus more pointedly on its ontological, epistemological, and ethical dimensions. Some comment on the conflicting interpretive grounding of Freire's primary theoretical sources in particular traditions in Marxism, existentialism, and Christianity, and they trace certain contradictions in the theory to the problems that arise when trying to weave those roots together. Such conflicts can be seen, for example, in Freire's conception of humanization as the ontological "vocation" of human beings. The theological notion of vocation undermines the more historicist ontological interpretation required when analyzing oppression (which Freire labels dehumanization), since it is also a way that humans produce the history and culture that they live. However much we may want to condemn dehumanization from an ethical point of view, we cannot ground this condemnation in an ontological claim. Similarly, Freire inconsistently historicizes his epistemological position, at times deploying a foundationalist view of knowledge or truth claims. Finally, Freire's effort to provide an ontological origin for his ethical ideal of democratic socialism necessarily founders on the logical conundrum of deriving "ought" from "is," and thus, his laudatory ideals require independent ethical and political justificatory arguments that he failed to offer.

Despite the force and range of the critiques of Freire's theory, it has continued to animate the thinking of a wide variety of scholars and activists. This is because he wrested penetrating insights from the opaque workings of history and from his relentless critique of his own practice. Freire argued that what mattered was not so much the consistency and durability of his theoretical formulations but far more the ethical coherence of his relationships with others and his commitments to improve the lives of the least advantaged. On this measure, none can doubt that Freire was above reproach.

Limits to Common Practices Claiming to Enact a Critical Pedagogy

Despite frequent protestations from Freire and other scholars, common practices claiming to enact a critical pedagogy based on his theory in fact domesticated or elided its most important elements. His praxis-oriented concept of dialogue has been widely misinterpreted to mean a kind of individualistic give-and-take conversation between teachers and students, as if simply giving each student a chance to speak and taking turns among speakers would somehow produce effects that could transform the dominant ideological structures of oppression (which reach into even the most humanistic and emancipatory classrooms). Liberation from oppression requires strategic "limit-acts" undertaken by organized collectivities, and dialogue is the form of praxis through which such acts are imagined and embodied. Freire's critique of banking models of education have similarly been misinterpreted to mean that teachers should never lecture or that they did not have a duty to share their expertise and direct certain aspects of learning. He insisted that teachers had a professional responsibility to be knowledgeable in their discipline and that they have the pedagogical expertise to construct learning environments and to pose questions that could unveil the reality of everyday life and draw students into a critical engagement with their learning and with the lives (history and culture) they were producing. Freire insisted on the moral and political equality among teachers and students, but he critiqued the false inferences to their epistemological and pedagogical equality.

Despite the limits to common so-called critical pedagogical practices and the deep misinterpretations of Freire's theory on which they are based, it is an undeniable truth that countless classrooms have become more humane as committed progressive teachers pursued the compelling dream that Freire articulated.

Freud, Sigmund

Known as the founder of the movement, theories, techniques, and clinical practices of psychoanalysis, Sigmund Freud (1856–1939) was one of the most influential figures of the 20th century, who revolutionized our understanding of the mind and its realms of the unconscious and the conscious, and of sexuality. He viewed each of us as being a stranger to ourselves and proposed a depth psychology that grappled with the conflicts that lay hidden from us—between love and hate, happiness and unhappiness, history and memory, life and death, and union and separation. Freud perceived psychological suffering as emerging from the loss of love and from forgotten or repressed incidents from the individual's childhood history. Recognizing the psychological fact of the human's slow maturation, and prolonged helplessness and vulnerability to others, Freud had education as a motif running throughout his work.

Freud identified the unconscious and its pleasure principle as the source of our significant, though unknown, motives for action, thought, and perception. He found that unconscious desires were expressed in dreams, slips of the tongue, jokes, and everyday mistakes, and he treated perception as passionate, that is, not as a neutral faculty but as oriented to wishes. Awareness or consciousness of one's own mental acts, he argued, is the exception in mental life. Freud then raised the novel question, what are the unconscious attitudes and history of mental development beneath the surface of behavior?

Biography

Subjectivity is the starting point of psychoanalysis, and Freud's biography is relevant to the design of his theory; those approaching his work can avoid neither his life nor his surprising admissions and his usage of his own self-analyses.

Freud was a Viennese Jew, deeply affected by the anti-Semitism of his time that culminated in National Socialism's rise to power and the death camps. In 1938, he went into exile, living his last year of life in London. In his youth, he had studied medicine at the University of Vienna, from 1873 to 1882, following which he became a researcher in physiological science, and by 1886, in partnership with Josef Breuer, he began a psychotherapeutic practice treating hysterics. With his patients, he created "the talking cure," and, against the current of his time, he left the method of hypnotic suggestion behind and instead interpreted illness as communicating a story of suffering that could be revealed through the patient's words. This orientation led him to design the method of free association, in which he requested patients to say anything that came to their minds without censoring their thoughts, and he asked them to report their dreams.

His interest in archaeology provided a metaphor for this realm of the unconscious—it could be understood as fragments of forgotten impressions buried and so preserved. His research revealed that childhood events were formative, but he also recognized that many of these events were subject to infantile amnesia; one of his most contested ideas was that memory and forgetting are two sides of the same coin and that we act out or compulsively repeat what cannot be remembered. In other words, the meaning of actions and mental representations cannot be revealed by the actor's intentions, since the human faculty of reason too is subject to an unconscious psychology of motives.

In sum, then, Freud's psychoanalytic theory depicts the mind as dynamic and multilayered, with much of a person's behavior driven by the inner unconscious realm and by the associated desires and drives. The terminology he used within this theory eventually saturated the vernacular and is now widely familiar.

Freud's psychoanalytic writing—23 volumes and an index, known as *The Standard Edition*—is a cornucopia of topics and styles. He wrote case studies of his therapeutic practice and wrote papers on psychoanalytic techniques, metapsychology, and group psychology; he made studies of art and literature; he discussed war, nationalism, and death; and he wrote histories of the psychoanalytic movement, lectures for popular audiences, and historical studies on mythology and religion. Peppered throughout this work are his key concepts along with the problems they identify: sexuality, the Oedipal complex, the meaning of dreams, the roles played by the unconscious, the psychical world, transference love, and symptoms of illness such as neurosis, psychosis, anxiety, resistance, and psychological defense mechanisms. He blurred the lines between health and illness and sanity and madness and considered that if love holds the person together, its loss causes him or her to fall apart. (Freud maintained that there are three sources of human suffering: loss of love, loss incurred through historical and natural disasters, and loss of the self; the loss of love was the most

painful.) He defined "the cure" as the capacity to work, to love, and to tolerate the myriad losses that reality incurs.

Major Theoretical Themes

Freud developed two theories of the mind. The first, called the *topological model*, posited that the mind had three layers—the conscious, the preconscious, and the unconscious. By 1920, his second structural model (compatible with the first) proposed dynamic interacting psychical agencies that he called the ego ("the I"; German, *Ich*), the id ("the It"; German, *Es*), and the superego (German, *Über-Ich*) (the latter two being, respectively, the unconscious and instinctual portions of human nature and the set of sociocultural norms and strictures that individuals acquire usually in childhood and that act as a form of moralizing conscience). The new problem that arose here concerned the nonunitary or divided nature of the subject. This led Freud to focus on the realm of human affect (feelings and emotions) through its major indicator—anxiety as fear of loss of love; he then took on the emotional volatility of the internal world. Late in his theorizing, Freud viewed the ego as being formed through its history of identifications and held that it is subject to three dangers: (1) internal pressures emanating from the id, (2) the demands of conscience and feelings of guilt coming from the super-ego, and (3) forces from the external world. For Freud, the ego was a creature of compromise, and its work involved perception, reality testing, judgment, thinking, and the handling of incompatible thoughts. Its strengths were also areas of its vulnerability.

Freud's theoretical breakthrough had emerged from studying his own dreams as a portal to his unconscious mental life. While the interpretation of dreams can be traced back into antiquity, Freud saw dreams as the royal road to knowledge of the unconscious. He recognized that they had two layers of competing meaning: (1) the manifest and (2) the latent. His method of interpretation of the latter took into account the dream world's method of disguise—dreams expressed forbidden wishes, but these were highly disguised through the "dream work" of condensation, displacement, reversal, substitution, and representation. He came to understand that, as well as in dreams, the unconscious erupts in bungled actions, linguistic errors, jokes, accidents, forgetting important details, and everyday mistakes.

Another breakthrough came with Freud's approach to sexuality, which he regarded as beginning with the infant's bodily erotogenic zones, stimulated by parental care and love. Oral, anal, and genital experiences orient the child's precocious sexual researches and inaugurate curiosity toward where babies come from, the difference between girls and boys, and an interest in parental sexual life. The complexities Freud ascribed to children and his insistence on their search for truth and knowledge inaugurated the new fields of child psychoanalysis and psychoanalytic pedagogy. The idea that sexuality comes early, and is both precocious and polymorphous in perversity, expands the concept of sexuality—it becomes related to the capacity for curiosity, imagination, intellectual life, sublimation of the drives, and the desire for knowledge of others.

These grand themes of the unconscious and sexuality led Freud to grapple with issues such as why we follow authoritarian leaders and what is the impact of group psychological life on the individual; here Freud's theories of the subject and intersubjectivity become significant for education, by way of the idea that even as one is in the throes of identification with the rivalries and demands of group psychological life, by narrating this as a story one can gain distance from its projections, compliances, and authoritarian tendencies.

Applying psychoanalysis to social problems requires a facility with Freud's theories and imaginative flexibility. Consider, for example, the nature of human culture. Freud found this to be the source of what is tragic in the human—aggression, the proclivity toward violence, and his postulate of the impulse he called Thanatos, or the death instinct, socially sanctioned by war, nationalism, and narcissism of minor differences. While his study on civilization and unhappiness asked again about love and hate and how happiness in a cultural context is possible, he nevertheless considered culture as a powerful force in sublimating aggression.

The strengths of Freud's theories are also their weaknesses—and a close reading reveals that he took an interest in these. His work resided in speculations, hypotheses yet to be proved, and imaginative leaps that took him beyond the limits of experience. Readers bring strong views to Freud, and there are common tendencies to dismiss Freud through clinging to one's own experience, psychoanalyzing Freud's motives, and concluding that Freud reduces all human reason to psychological processes and to pansexuality. In Freud's favor, no one can settle the problem of where misery or discontentment comes

from and why education both induces anxiety and creates the means for its symbolization.

Froebel, Friedrich

The German educator Friedrich Wilhelm August Froebel (1782–1852) was among the most important educational theorists of the 19th century. Today, he is primarily known as the founder of the idea of the kindergarten. The son of a Lutheran minister, he was profoundly shaped by his early religious experience. While his religious beliefs were at first quite orthodox, he eventually embraced a highly spiritual and pantheistic view of the world in which the forces and manifestations of Nature literally revealed the truths of religion and the meaning of God. As he explained,

> Nature presents the truths of religion in visible form, and confirms what we learn by meditating upon God. What we thus conceive we find existing in the material world. So it is that nature satisfies the demands of religion. For like all that exists, nature reveals God. (Froebel, 1912, p. 97)

Like his Swiss mentor, Johann Pestalozzi (1746–1827), Froebel felt that children had unique needs and potentials that required careful development and nurturing. According to him, children should begin to be educated shortly after birth. Learning would then continue as a lifelong process. His model emphasized not only hands-on learning for children but also their development of a spiritual understanding of the world.

Froebel's educational philosophy is most clearly outlined in his 1826 book *The Education of Man*, in which he described God as a "Divine Unity" who connects all living and inanimate things through the divine spirit. Ideally in his system, children would be taught to observe and understand the world in which they lived. Learning involved being, as much as possible, one with Nature. This model contradicted the notions of philosophers such as John Locke (1632–1704), who believed that the child was a vessel to be filled with specific information and knowledge by the instructor or teacher. This idea that the child/learner should not have ideas forced on them explains, to a large extent, why Froebel appealed to more modern educators such as the American progressive John Dewey (1859–1952), who emphasized learning as a process of exploration and self-discovery for the child.

Froebel opened the first kindergarten in 1837 in Blankenberg, Germany. Many of the ideas he developed for the school were a direct outgrowth of his two-year apprenticeship as a forester, as well as the time that he worked as a mineralogist in the Royal Museum in Berlin. From his work as a forester, Froebel almost certainly developed a greater sense of the spiritual elements found in the natural world, while his work as a mineralogist probably made him more aware of patterns found in Nature. Both of these ideas—that is, the spiritual connection between things and the patterns found in Nature—were key concepts for his kindergarten curriculum, which was loosely described as the "Gifts and Occupations."

These "Gifts" and "Occupations" were a series of activities intended to provide the child with a clearer understanding of how the world works. Many of the activities were not just practical but also deeply spiritual in nature. Twenty in number, they were ranked in terms of their complexity and difficulty. The Second Gift, for example, physically demonstrated the German philosopher Georg Wilhelm Friedrich Hegel's (1770–1831) dialectical theory of thesis ← → antithesis = synthesis. This idea, which argues that through the conflict/friction of opposites a synthesis emerges, was not only a key philosophical concept for 19th-century philosophical thought, but

manifests itself in the writings of later figures such as the political philosopher Karl Marx (1818–1883). The Second Gift specifically demonstrated Hegel's theory by employing a three-inch wooden sphere, a cube, and cylinder. The child would feel the wooden sphere (often blindfolded), making note of its roundness, and then feel the cube with its flat linear sides. Finally, he or she would explore the cylinder, which is a synthesis of the sphere and the cube, being both round and flat, properties (the synthesis) that conform strictly to neither the sphere nor the cube.

Many of the Gifts and Occupations have become commonplace in various forms in early childhood education and culture. Sadly, they are used today with little knowledge of their origins with Froebel and the kindergarten. For example, the Third through the Sixth Gifts are a set of building blocks, whose sophisticated design provided the basis for the Unit Block system that is in widespread use in early childhood settings today. Likewise, the flat parquetry squares and triangles that were used in the Seventh and Thirteenth Gifts are commonly used in contemporary classrooms as part of mathematics instruction (tessellation). The Nineteenth Gift is a primitive Tinkertoy-like set made of cork balls and toothpicks, which demonstrates to the user basic engineering and structural forms.

Froebel's work is largely neglected in our own era. His connection to the modern kindergarten is distant at best. This is unfortunate, since he has a great deal to say to contemporary educators. Like the more recent anthropologist Gregory Bateson (1904–1980), Froebel was interested in the "pattern which connects all the living creatures." In Froebel's case, this manifested itself in the form of God. Such an approach need not necessarily be religious but can be ecological in Nature—one that involves how all things in Nature are interconnected and related to one another in the larger phenomenon we call Life.

Gandhi, Mahatma

Human societies have evolved through the cumulative contributions of their members. But some individuals stand out for their unique contributions to the enrichment of human life and the positive transformation of society. Luminaries such as Leonardo DaVinci, William Shakespeare, Isaac Newton, Charles Darwin, Albert Einstein, Ludwig Beethoven, Leo Tolstoy, Nelson Mandela, and Bertrand Russell come to mind. Their life journeys inspire some and evoke debate among others. Mohandas Karamchand Gandhi (1869–1948) continues to evoke both reverence and hatred. By looking at his life, we can gain some understanding of how he changed the lives of Indians during British colonialism, and we can see how his ideas continue to be relevant in this age of globalization. Gandhi saw the purpose of education not simply in terms of acquiring knowledge but as the building of character. He believed that education was a liberating force that required the development of body, mind, and spirit. His belief in the power of education was an important element in his campaign for Indian self-rule.

Gandhi's name, however, is inextricably associated with nonviolence, and the model offered by his life in this respect is widely studied in peace education programs. However, equating Gandhi with nonviolence in a narrow sense would be missing the essential Gandhi—to know him in this way, as we need to know not only what he achieved in his life but also how he lived his life. Since his life is his message, as he put it, this entry is an attempt to provide a brief but panoramic view of Gandhi's life in order to drive home his essential message.

Born and educated in India, Gandhi earned a law degree in London and moved to South Africa in 1893 on the invitation of a client to provide legal assistance. There he experienced firsthand the indignity of racism directed at both Blacks and minority Indians. He decided to fight this injustice, and the struggle kept him in South Africa until 1914. He had experienced racism in London, but South Africa was different. The shocking experience of being thrown out of a first-class train compartment even though he had a valid ticket, the insult of the nonrecognition of Indian marriages by the state, the humiliation of being forced to carry identity cards, and, of course, the naked racism practiced against the Blacks—all these exposed Gandhi to new challenges. He decided to stay and take these challenges as an opportunity. He launched a civil disobedience movement in South Africa. This was the beginning of a lifelong struggle to learn how we ought to live our lives. It was the beginning of what he would call his "experiments with truth."

The Making of the Mahatma

Truth (*satya*), nonviolence (*ahimsa*), and nonattachment (*aparigraha*) are cornerstones of Indian philosophy and religion. Gandhi grew up in a religious

environment where these exerted great influence. Beginning with his stay in London, he was also influenced by the Bible; the Indian scripture, the *Bhagavad Gita*; John Ruskin's *Unto This Last*; and the writings of Leo Tolstoy. Gandhi paraphrased *Unto This Last* and decided it pointed in the direction of a life worth living. The welfare of all became his life's goal and sacred duty (dharma).

Gandhi adopted a life reduced to minimum necessities, and he worked his influence on his wife, Kasturba, at the same time. She went to jail to protest South African leader General Jan Smuts's nonrecognition of Indian marriages. This was a turning point for Gandhi, and he began the process of transforming ancient Indian ideals into concrete programs of action. With truth and nonviolence as his uncompromising moral principles, he launched his civil disobedience movement and experimented with the use of satyagraha (soul force) as a constructive weapon for waging nonviolent struggle against oppressive regimes. Satyagraha means insistence on truth, and the ideal satyagrahi possessed inner strength and the ability to face physical oppression inflicted by his or her opponent.

Gandhi lived in South Africa for more than 20 years—the most revolutionary and transformative years of his life. While it was not until much later that the Indian poet laureate Rabindranath Tagore gave Gandhi the title of "Mahatma" (Great Soul), in reality, he became that person in South Africa. There is a saying in South Africa, "India gave us Mohandas and we gave them back a Mahatma."

The Mahatma in India

Aboard a ship on his way from London to South Africa, Gandhi wrote down his dream of a free India, published in 1909 as *Hind Swaraj*. He returned to India in 1915 and led the freedom movement, which was based on massive participation of Indians. Millions identified with him and were able to grasp his method of satyagraha. He identified with Indians facing a wide variety of problems and tried to provide them with hope for change. People were drawn to him, lining up at railway stations and roadsides to get a look at him. When he built his residence (ashram) in Ahmedabad between a cemetery and a jail, he commented that this was the right place for a satyagrahi, one who is prepared to suffer and die for a good cause.

Although Gandhi was a prolific writer, he communicated with the people directly, traveling widely in the country. He also introduced the use of the spinning wheel, which was as much a political and ideological symbol as a real indigenous-based economic tool meant to alleviate suffering.

As a freedom fighter, Gandhi did not spend all his time rallying against the British Raj; a good deal of his time was spent rallying Indians for true independence (swaraj), awakening them to their own, homegrown social ills, which, he said, had chained Indian society. He launched a host of social reforms, each of which earned him a separate group of enemies. The programs included the spinning wheel and the *swadeshi* movement, eradication of untouchability, the welfare of the harijans (*dalits*), Hindu–Muslim unity, protection of animals (in particular, cows), agitation against liquor, and promotion of women's empowerment. For Gandhi, political freedom from British colonialism and freedom from repressive domestic social evils went hand in hand.

Gandhi drew strength from many religions, considering himself both an Indian citizen and a citizen of the world. If truth, nonviolence, and satyagraha (soul force) were the foundation of his struggle, then swaraj (freedom), *swadeshi* (self-reliance), and *sarvodaya* (welfare of all) were his life's goals. He introduced a new, apprenticeship-based system of basic education (*nai talim*) and experiential learning, the relevance of which has been stressed by many educators. Gandhi's India resided in her 7,000 villages, and his dream of a free India was based on the foundation of a decentralized, self-reliant village economy rather than on a centralized, top-down bureaucracy.

The Broad Message

Gandhi believed in simplicity of living and the reduction of wants to basic necessities. He believed that unchecked greed is unsustainable. "The earth," he remarked, "produces enough for everybody's need but not for everybody's greed."

Gandhi also believed in community, a life based on sharing and sacrifice. He implemented his vision first with his family. Gradually, his ashrams exemplified it; and it was adopted by his satyagrahis.

Gandhi spoke of freedom from fear. He insisted that no one can rule us without our consent. Many found his actions of breaking unjust laws and pleading guilty with consequent personal suffering both heart wrenching and empowering at the same time. When he would be arrested and put in jail, people would demonstrate en masse, get arrested, and fill the jails. This led both to the loss of fear of jail and to the jails becoming useless as a means of suppressing dissent.

Gandhi was a hands-on man with a clear goal and a long-term vision of what he wanted to achieve. He also believed in forgiveness. There were many times when he was manhandled or beaten. He was forgiving both because he was a genuinely forgiving man and because it freed him from unnecessary distraction. While a proportionate response to violence may seem just to many, violence was violence to Gandhi, no matter how it came about; he believed that seeking an eye for an eye would make "the whole world blind."

Gandhi spoke of "the universal law of love." He claimed to have no enemy. Holding no office, he represented the conscience of millions. He had a strong confidence in struggling with the right means and not worrying about the outcomes. He insisted that "fair means alone can produce fair results."

The Essential Message

Gandhi had no invention, no creation. Even nonviolence was, as he said, as old as the hills. But he took what was old and gave it power for the present. The tradition of nonviolence was essentially a moral and spiritual tradition in India: He added to it the power of concerted, strategic, mass action for social change. He was dealing with the question of how we should live, and his answer insisted on *action*.

Gandhi was loved by millions and called Bapu (father); he was revered by millions and called Mahatma, although few who revere Gandhi today wish to live like him.

Gandhi saved the tradition of nonviolence from political irrelevance. It became his cornerstone for humanity's quest for justice and peace. Coming on the stage when the Industrial Revolution was at its peak and humanity was challenged by the machine, a time when nations were sliding into world wars, Gandhi challenged modernity by indicating a different way forward. To show this way, he turned his life into an experiment for the world to see—both successes and failures alike—and became a mirror to the world. As he said, his life is his message.

Gender and Education

The rise of gender as an issue of concern for social research, policy, and practice has had a major impact on the field of education. While typically associated with a strong policy and practice agenda to address gender-based disadvantages, the gender and education couplet has also fueled a diverse range of theoretical and empirical scholarship. This has brought new perspectives to understandings of the purposes, effects, and experiences of education and shown the importance of questions to do with identity, sexuality, and relational dynamics. Of course, gender existed as a differentiator and marker of educational experiences and outcomes prior to the 1970s and the rise of second-wave feminism. The significant turning point lay in identifying such differences, and gender itself, as matters that warranted scholarly and policy attention. This entry discusses the study of gender inequality in education, the influence of feminism on education, the use of the term *gender* in educational research, and the influence of poststructuralism in research on gender. It then discusses the increasing research on boys' educational experience during the 20th century, as well as more recent and emerging issues in research on gender education.

Education has been a central site of feminist inquiry, examined for its part in (re)producing gender-based inequalities, for promoting changes in gender identities, roles, and relations and for questioning the construction and effect of gender normativities (Arnot & Mac An Ghaill, 2006). A significant legacy of early feminist interventions was to interrupt commonsense views about gendered experiences and futures, by identifying some differences as not natural and acceptable but

as social problems and inequalities that demanded redress. Gender differences in subject preference, postschool aspirations and destinations, informal social and interpersonal practices, and so on were noticed as problems, as reflecting a gender order that produced advantages and disadvantages (McLeod, 2004). How such differences were and are conceptualized, and their sources and effects analyzed, continue to be debated, contributing to the emergence of a rich and varied field of educational scholarship.

While one might hesitate before claiming feminism's influence on education as universal, its impact is far-reaching. Gender equality as a formal aspiration is enshrined in policies in developed and developing countries and in the goals of international agencies such as the United Nations. The *United Nations Millennium Goals* include the target to "Eliminate gender disparity in primary and secondary education, preferably by 2005, and in all levels of education no later than 2015" (United Nations, 2010). Improving gender equity and access has been an important but not the only strand of research and policy. Gender and feminist scholarship has also addressed the epistemological, ethical, and relational dimensions of education. This encompasses making problematic what has counted as worthwhile knowledge, according serious attention to the effects and forms of interpersonal relations, and examining the intersecting practices and processes that shape gendered identities across diverse educational sectors and settings. Much debate within the field of gender and education is characterized by struggles over how to recognize claims to difference and claims to equality—with reference to differences between genders and differences within gender groups. Does recognition of gender differences weaken claims for equality? Does equality demand sameness, or can equality accommodate difference? Responses to such questions have fueled extensive theoretical and philosophical debate and shaped feminist educational reforms.

Sex, Gender, and Identity

The term *gender* typically signals an attention to the socially formed nature of male and female identities, relationships, and orientations. This contrasts with earlier uses of the term *sex* to denote differences between males and females, which often assumed such differences to be fixed or natural. In educational research from the early 1980s onward, gender began to replace sex as the preferred descriptor of male/female identity differences, reflecting debates within feminist and social theories that looked to the social and discursive dimensions of identity. In the sex-differences mode, researchers tended to assume that the category of sex was stable, and research was concerned to investigate its effects. In the gender-research approach, attention has been more on investigating how patterns and forms of differentiation are produced, and consequently, it has helped spawn a large body of research concerned with processes of gender construction in education.

Important shifts in conceptualizing difference and identity in the field of gender and education can be schematized as follows. Notions of sex role and socialization marked second-wave feminism, and in education, this translated into a concern with investigating sexism, nontraditional roles, and equal opportunities. Reflecting the influence of socialization theories and symbolic interactionism, identities were seen to be much like social scripts, and with the right messages, nonsexist roles were possible. The 1980s saw a turn to focusing on specifically feminine and masculine ways of being in the world, reviving in some respects notions of inherent, embodied gender differences—but with a positive inflection. Influenced by ideas from cultural feminism and feminist psychology and philosophy (see, e.g., Gilligan, 1982; Martin, 1986), educational researchers explored distinctive feminine learning styles, pedagogies, and knowledges, seeking in part to recast understandings and expressions of femininity not as something to be ignored or erased in the educational conversation but as integral to it and as deserving recognition and value. On the one hand, the turn to "difference" in education promoted relatively conventional ideas about masculinity and femininity and of gender relations. On the other hand, it encouraged a more nuanced account of the heterogeneity of gender identities. Notions of intrinsic difference were challenged in the 1990s by a sustained focus on gender as a social or discursive construction, thereby placing analytic attention on the circumstances and conditions that produced or shaped gender identity. If gender was social, then it was open to change and variation. The conceptual binaries of natural and social, as with those of difference and equality, present ongoing dilemmas for gender researchers in education, reflected as well in

the focus and rationale of policy reforms, navigating between, for example, noticing or not noticing gender as a category of concern or seeing gender differences in learning styles and aspirations as amendable to intervention.

Gender and Other Factors

Concurrently, feminist theory was shaping and being shaped by the wide range of ideas and analyses that come under the banner of poststructuralism, which provided an influential theoretical approach for understanding gender and subjectivities. Within education and beyond, it generated large bodies of research addressing the diverse ways in which gender identities and relations were not natural or essentialized, and/or stable or singular, but rather they were multiple and contingent, and/or produced and performed. These ideas have provoked considerable debate, often leading to polarized positions, which remain influential today. At one end of an imagined continuum, poststructuralism is seen as signaling political inertia, driven by antiessentialism and discourse determinism that undermines the very category of "woman" and concepts of agency. While some feminists lamented that poststructuralism was bad for women and bad for politics, other feminists challenged the very formulation of such a view of (feminist) politics and of subjectivity, arguing that such critiques represented not a repudiation of the subject but an interrogation of its construction as foundational (Butler, 1990). Here, poststructuralist arguments were brought to challenge some of the foundational narratives of feminism itself, and this too was felt across gender researchers in education. At the other end of a continuum, feminism and poststructuralism were seen as pursuing potentially complementary lines of analysis, both posing skeptical and deconstructive questions to normalizing practices and working to destabilize taken-for-granted truths—of gender subjectivity, of gender relations and relations of power, and so forth (St. Pierre & Pillow, 2000).

The spread of these ideas accompanied a growing unease about the ethical and political effects of addressing gender in isolation from other social and identity categories, fostering more sustained attention to differences within gender categories, and a focus on the social and subjective effects of intersecting differences—of race, ethnicity, class, sexuality, disability/ability, age, and religion. Often called "intersectional analysis," it examines relations between different dimensions of identity—of class and gender, or race and gender—reviving critiques of the universalism of gender or tendencies to homogenize gender-based inequalities and experiences in education (Ali, Mirza, Phoenix, & Ringrose, 2010). Questions of sexuality, homophobia, and heteronormativity were placed firmly on policy and scholarly agendas. While these matters had been central in earlier second-wave feminism, particularly among radical feminists, the poststructural and intersectional turns helped give renewed emphasis to the multilayered dimensions of gender as a social relation and an identity. At the same time, there is some evidence to suggest that gender, as a focus for sustained policy focus, as relevant to professional knowledge, or even as relevant to scholars beyond the field identified as "gender and education" research, is no longer as prominent as it has been in the preceding decades. This is likely due to many factors, not least the views that gender inequality is not the problem it once was, that there are demonstrable improvements in the circumstances and opportunities of some women, and that feminist agendas, both scholarly and professional, have now been mainstreamed.

In the final decade of the 20th century and into the next, growing concerns about the educational experiences and outcomes of boys led to what has been characterized as a "boy turn" in gender and education research (Weaver-Hightower, 2003). For some, this represented a backlash against feminist gains, for others, it was about giving equal attention to boys, to correcting the imbalance of attention on girls and women, when—this argument said—there had already been substantial, if not too much, feminist, progirl activity. A proliferation of research and polemic ensued, informed by a mixture of ideas about forms of social and educational fairness and equality, and often reviving notions of natural difference between the genders. Many feminist and profeminist educators have regarded these interventions as counterproductive and based on flawed or limited evidence. However, one less remarked-on effect is that arguably these debates also contributed to unsettling understandings about gender and education, forcing a critical refocus on the relational dimension of gender and education as a field of policy, practice, and lived experience. At the same time, scholarly work on masculinity, and the influence of concepts such as "hegemonic masculinity" (Connell & Messerschmidt, 2005), have been crucial in expanding the sense of what matters as part of the gender and education field,

and in encouraging critical analysis of (structured) relations of privilege and subordination, not simply as patterns and points of gender differences.

Current and Emerging Issues

Contemporary scholarship in gender and education is characterized by a degree of theoretical diversity, engaging with and informed (by and large) by social science—including psychological fields—and humanities traditions. However, the influence of social constructionism and of poststructuralism—in both their "weak" and "strong" versions—continues to shape much work. Maintaining robust theoretical diversity and dissension is an important challenge. So too are the challenges posed by engaging with the far-reaching effects of globalizing processes and transnational flows of ideas, people, and capital. Gender and education scholars, along with others, are increasingly looking beyond the concerns and theories emanating from the global north and west to heed the challenges and questions posed by nations and regions that have usually been on the edges of such discussions, unless introduced via gender and development discourses (Connell, 2011). Discussions of spirituality and religion are on the rise, notably in relation to the politics of exclusion, questions of tolerance, identity and difference, and responses from national systems, schools, and curriculum programs to expressions of religious diversity. Expanding research on sexuality and sexual politics, developing insights from queer theory, and giving more visible attention to lesbian, gay, bisexual, and transgender issues are important in current agendas. Many longstanding issues command and demand ongoing attention—most particularly, in relation to gender-based violence, bullying and harassment, and the emotional, affective, and relational dimensions of education—those of community and care and concern for others (Lynch, Baker, & Lyons, 2009). In the contemporary period, gender is mainstreamed as a category for data collection and for auditing access and participation, yet in many parts of the world, it is simultaneously at risk of disappearing as a priority focus for educational policy and reform. Grappling with such complexities in the present are part of the making and remaking of the field of gender and education.

General Systems Theory

See Accountability and Standards-Based Reform; Complexity Theory

Globalization and World Society

Globalization is a term frequently used to capture the reality that diverse peoples of the world are increasingly economically, politically, and culturally interdependent. Numerous scholars have called attention to how advances in communication, transportation, and computerization have fundamentally altered human existence, to the extent that we might describe contemporary human societies as networked societies. Along these lines, globalization has been characterized by scholars such as David Held and Anthony Giddens as the reduction of time and space such that happenings in one part of the world hold the potential to implicate people in other parts. Although globalization most recently is linked to the technological advances of the middle to the late 20th century, the actual dawn of widespread contact across distant regions of the world dates back to earlier developments, mostly linked to the emergence of worldwide trade, such as the emergence of the Silk Road and the rise of transoceanic shipping. Such developments also contributed to the rise of colonialism, which, for some, might be seen as the dark side of globalization. On the other hand, globalization creates a demand for new conceptions of citizenship and so serves as a challenge to educators and to philosophers of education.

Evolution of Globalization

Globalization brings greater numbers of peoples into contact, largely creating two competing possibilities: (1) the potential for domination by more powerful groups (typically operating as extensions of particular nation-states) or (2) the possibility for forms of cooperation consistent with the ideal of a world community or society. There are many examples of both outcomes. In terms of domination, examples include the rise of the great European powers in the 16th and 17th centuries, whose advanced shipping industries and great navies served to colonize vast regions of the world. The emergence of the United States as a world power, and in particular the deployment of its military to further its own economic interests, has been described by Noam Chomsky and Gore Vidal in a manner consistent with forms of domination and imperialism. The same may be said of the former Soviet Union and its domination of parts of Asia and Europe.

As for the emergence of a world community in which nation-states collaborate toward common goals, an obvious example is the founding of the United Nations in 1945 to promote world peace and security. A key facet of the peace-serving mission of the United Nations is served by its International Court of Justice. Other regional and global organizations also tend to fit the world society ideal, including, most recently, the development of the European Union and economic entities such as the Organisation for Economic Co-operation and Development, the World Bank, the International Monetary Fund (IMF), and the World Trade Organization (WTO). Here, though, the ideal of a world society gets somewhat convoluted; some critics argue that the WTO and IMF, among others, actually serve the interests of world economic powers and, consequently, may be better understood as vehicles for domination rather than cooperation. The counterargument offered by supporters of such organizations is that the world benefits when common economic policies are followed, such as when all nations are compelled to eliminate trade barriers (protectionism) relative to specific industries.

Critics of Globalization

Obviously, positions vary on the role of organizations such as the Organisation for Economic Co-operation and Development, World Bank, WTO, and IMF. Official meetings of these organizations, and others such as the G-8 (Group of Eight), have attracted significant opposition, reflected in many cases by massive street protests like those at the WTO 1999 summit in Seattle. These forms of oppositional movements have been described as "antiglobalization" movements, but in fact, they tend to be in opposition to a particular strain of globalization, described as neoliberal globalization (or neoliberalism), so-called because of the focus on advancing free markets through liberalizing

global trade (hence, the "new" liberals or "neo" liberals). Neoliberalism generally is seen to be consistent with the fundamental teachings of Milton Friedman (and his followers known as "the Chicago Boys") and initially was advanced at a global level largely through the political leadership of Ronald Reagan ("Reaganism") and Margaret Thatcher ("Thatcherism"), both of whom advocated a global marketplace with limited governmental interference. Supporters of this economic philosophy tend to see open markets as a better source for enacting just social policies, as opposed to government officials, represented by various political and economic interests, making such decisions on the basis of taxpayer-generated revenue. Reagan's famous quote that "government does not solve problems; it subsidizes them" tends to be consistent with this line of thought.

Although many scholars approach analyses of globalization in economic and political terms, others instead focus on its cultural facets or what might be described as cultural globalization. A common refrain is that societies are becoming more homogeneous, with some arguing that the world is undergoing a form of "Americanization," "Westernization," or "McDonaldization"—the latter reflective of an argument advanced by George Ritzer. Other scholars reject the idea of a world culture emerging under the influence of the West and instead point to the hybridization of cultures and societies, drawing to some extent on the work of Edward Said among others. Scholars subscribing to this perspective, including Allan Luke and Carmen Luke, note examples of localized cultures accommodating global influences, but often on their own terms and in unique ways. Such a perspective suggests a certain level of empowerment among localized populations, an argument largely absent from discussions of globalization as a form of Western domination. The Westernization argument also tends to ignore the influence of cultures originating from other regions of the world; a notable example here is China's widespread influence around the world.

World Community and Global Citizenship

The ideal of a world community also suggests particular notions with regard to citizenship. Terms such as *cosmopolitanism*, *world citizenship*, *global citizenship*, and so forth have proliferated over the past three decades among social theorists concerned with the changing context of the nation-state. Just as the term *globalization* has a much longer history than is typically acknowledged, notions of world or cosmopolitan citizenship also date back to a previous age. For example, within the context of Western intellectual thought, cosmopolitanism may be traced back to the ancient Greeks, with later updates offered by Enlightenment thinkers. But again, the emergence of highly interdependent networked societies has increased the emphasis on notions of world citizenship.

Some writers argue that as nation-states lose influence over global affairs, giving way in part to multinational enterprises, intergovernmental organizations, and nongovernmental organizations, forms of global citizenship are needed to fill the void left by a declining sense of nationalism and national citizenship. Anthony McGrew, for example, argued that the territorial model of liberal democracy is increasingly challenged by globalization. Consequently, new forms of citizenship highlighting universal rights and responsibilities disconnected from a particular geographic locale (or nation-state) are increasingly needed. A point of emphasis here is the call for worldwide recognition of basic rights for all human beings, advanced to a great extent by a range of social movements (e.g., women's movements, children's rights movements, environmental movements, etc.) and supported philosophically by the Universal Declaration of Human Rights adopted by the United Nations in 1948. Worldwide social movements aimed at advancing universal rights have been described as "globalization from below," which typically is contrasted with global initiatives advanced by powerful organizations and groups and described as "globalization from above" (typically associated with neoliberalism).

Advocates of a world society, often embracing the ideal of global citizenship, argue that contemporary challenges confronting the world's population are too great and complex for individual nation-states to resolve. Issues such as global warming, environmental degradation, widespread ethnic conflict, the proliferation of famine, the continued use of militarization as a form of conflict resolution, threats of global pandemics, among other worldwide concerns, require nations and their citizens, including key organizations and social movements, to work together as stewards of the planet and of peace. Along these lines, Robert Rhoads and Katalin Szelényi (2011) posited that we live in a world in which technology seems to have outpaced the

"social imagination and our ability to construct societies and social relations in a manner consistent with promoting world peace" (p. 6). They argued for a form of global citizenship that incorporates both a sense of world obligation (and rights as well) with a commitment to the local/national context; in other words, global citizenship represents a form of engagement in a larger world society but does not necessitate abandoning more localized rights and responsibilities.

Opponents of the world society ideal come from multiple ideological vantage points. For example, the far right in the United States often stands in opposition to global initiatives led by organizations such as the United Nations, maintaining that such intergovernmental organizations compromise the autonomy of the U.S. government and hence limit its ability to act in the interests of U.S. citizens. Criticism also arises from the political and ideological left, but here, the attack is mostly directed at the neoliberal strain of globalization. Chomsky has been a major voice among such critics, arguing that the neoliberal version of the world order places corporate profit over people. Opponents argue that neoliberals tend to promote global policies favoring corporations and large investors, reflecting the perspective that a rising tide lifts all boats (a version of Reagan's "trickle-down economics"). The critics further argue that only the wealthy actually benefit from neoliberal policies, pointing to the growing gap between wealthy and poor nations, as well as wealthy and poor individuals within particular nations. Jerry Mander (2006) pointedly argued that "the model does not lift all boats, only yachts" (p. 8). For critics such as Chomsky and Mander, the neoliberal version of globalization that now dominates the world is unlikely to strengthen notions of a world society, given that it is seen as perpetuating inequality.

Contemporary forms of globalization involve the widespread reduction of time and space and offer the potentiality of a world society. However, opposing ideological and political perspectives confound any clear articulation of the world society ideal. While some advocate a world community governed by the values of a free market system, others see the need for forms of governmental intervention to address economic inequalities and social problems. And still others oppose any attempt at reducing the power and autonomy of their own nation's role in global affairs. As a result, theories linked to the world society ideal, and to related concepts, such as global or cosmopolitan citizenship, must reconcile a host of complexities and contradictions in the quest for clarity and usefulness.

"Gold Standard" Research: Controversies

See Educational Research, Critiques of

Goodman, Paul

Paul Goodman (1911–1972) was a public intellectual who is best known today for his 1960 book *Growing Up Absurd*, one of the primary influences on the New Left of the 1960s. Goodman rejected the common claim that the problem with education lay in the schools' failure to properly socialize students. To the contrary, Goodman argued that students were oversocialized and would benefit from the dismantling and decentralization of the public school systems. He proposed a number of small-scale experiments intended to take over the function of the nation's overwhelming, monolithic school systems, and provide authentic education, rather than babysitting and job training. While Goodman's work is largely forgotten today, he has recently received attention as the subject of the documentary film *Paul Goodman Changed My Life* (2011).

Born in New York City, Goodman graduated from the City College of New York in 1932 and received a PhD from the University of Chicago in 1953, writing a dissertation titled *The Structure of Literature*. Goodman's publications included several volumes of poetry and short stories; *Gestalt Therapy*, a book written with Frederick Perls and Ralph F. Hefferline; *Communitas*, a book on city planning coauthored with his architect brother Percival; and several books of social criticism published in the 1960s and early 1970s. He was a pacifist conscientious objector to World War II, a practicing psychotherapist, and an open bisexual who was one of the forerunners of the gay liberation movement of the 1970s.

While almost all of Goodman's work, including his fiction, included some reference to education, this entry will focus on two late works that express the culmination of Goodman's philosophy of education: *Growing Up Absurd* (1960) and *Compulsory Mis-Education* (1964). In both works, Goodman challenged the common view that problems like juvenile delinquency arise from a failure of socialization, from the youths' inability to adjust to society. Rather, youth were maladjusted because the society in which they lived was one into which it was not worth growing up. Thus, educational theory focused on adjustment to society will inevitably fail when that society lacks adequate opportunities for experience and growth.

Goodman was, of course, not alone in tracing the problems of education to larger societal problems. However, while the vast majority of educational theorists proposed programs designed to improve the public school systems, Goodman took nearly the opposite tack, advocating the elimination of compulsory education. Goodman was well aware of the fact that he was attacking a basic bulwark of Enlightenment values; after all, unless accomplishments like literacy are widespread, we cannot hope to escape our intellectual tutelage. But he found education as it currently operated more conducive to strengthening our intellectual dependence on society's elites than to helping us become part of an active, informed citizenry.

Our educational system is designed to construct good workers who have adjusted to society rather than citizens who, themselves, create society. Goodman further claimed that the function of the schools was to provide babysitting, useless administrative jobs, contract work, and students for education schools, as much as it was to educate. The school system was more of a training ground providing skills for employment than a system designed to create enlightened, active citizens; hence, the contemporary (1950s) focus on science education to keep up with the Soviets.

Goodman's proposals for alternatives to compulsory education cannot be understood without an understanding of his political theories, which were based in what we might call his "conservative anarchism." His anarchism was grounded in the general claim that centralized, hierarchical structures tend to be detrimental to human flourishing, while decentralized, open-ended structures tend to promote human flourishing. Goodman was open to certain exceptions to this general claim. Some aspects of society *might*, Goodman confesses, be more conducive to human happiness when organized centrally and hierarchically, but they were exceptions to the general rule. Goodman did not propose large-scale projects that would reproduce the problems of centrally organized institutions; rather, he suggests piecemeal experimentation that would directly involve citizens where they are most likely to be competent and where the consequences of failure would be contained.

Anarchism may be divided into destructive and constructive phases. In its destructive phase, anarchism attempts to destroy centralized systems of power, especially state power. In its constructive phase, anarchism builds up decentralized institutions as alternatives to the present centralized systems. Both phases can be worked on at the same time; one might work to undermine the power of the state while creating alternative institutions intended to take over the essential functions of the state. We have already seen Goodman's destructive phase: the elimination of compulsory education. The constructive phase is just as important to Goodman's philosophy of education.

Goodman proposes several alternatives to compulsory education at the K–12 level, as well as alternatives to de facto compulsory education at the college level. Regarding K–12, Goodman argues that the simple fact of making education voluntary may, in itself, be an improvement over the current system. He argues that freedom of growth is impossible without intrinsic motivation and that such motivation is stifled by forcing students to attend school. Goodman points to schools like Summerhill (modeled on A. S. Neill's theories), where the voluntary nature of the schools may tempt students to skip school but where their natural curiosity will draw them back to school, now eager to learn.

Alternatives to compulsory education need not be limited to schooling of the bricks and mortar variety. Goodman, as an inhabitant of New York City, found the city itself to be highly educative and thought that limiting education to the inside of four walls meant the loss of numerous educational opportunities. Teachers could simply walk students around the city where architecture, city planning, city history, factory production, and so on could be discussed in their natural environment. In a similar vein, Goodman also proposed (modeling off the GI Bill) giving the money that would have gone into the school system directly to students, who could use it for the educational purpose of their choice, which could include travel, scientific projects, or participation in experimental schools.

Greene, Maxine

The educational philosopher Maxine Greene (1917–) has spent her long, full life defying categorization and evading labels. At the risk of "boxing her in," it is safe to say that she is known primarily for her work in existential philosophy and aesthetics education. In fact, she was one of the earliest philosophers of education to devote a full book to the relationship between existential themes and educational theory/practice. Her volume *Existential Encounters for Teachers*, published in 1967 when she was an associate professor at Teachers College (TC), Columbia University, and editor of *Teachers College Record*, broke new ground, in both its content and its form. In this work, Greene introduces the teacher to the complexity of her role in the modern world through encounters with the writings of 19th- and 20th-century existential philosophers. Organized around themes of "The Individual," "Others," "Knowing," "Choosing," and "Situations," these encounters provoke the teacher to think more deeply about her particular identity and situatedness, about her responsibility to be authentic with her students, and about her possibilities for choosing for herself and for acting in the world. These themes have continued to inform Greene's work and life in profound ways for the past half-century.

Greene's own situation in the early 1960s as a young, Jewish, middle-class, intellectual female shaped and was shaped by her choices as she found her way in academia. Not unlike other women of her generation, gender bias and institutional sexism were her uninvited companions as she made

career decisions—including her choice of a PhD program. As she recounts in the video documentary *Exclusions and Awakenings: The Life of Maxine Greene* (Hancock, 2001), Greene needed to select a graduate program that would allow her to take classes while her young daughter, Linda, was in school. New York University's School of Education had the day schedule that she needed. It was at New York University that Greene studied the philosophy of education with George Axtelle, even though her major as an undergraduate at Barnard College was English and her aspiration was to write novels.

After completing her doctorate in 1955, Greene taught at Brooklyn College and Montclair State College in New Jersey prior to being hired by TC in 1965. TC has been her academic home since then, where she is now the William F. Russell Professor Emerita in the Foundations of Education. However, as Greene has noted, TC did not always feel like "home sweet home." As one of the first women of her generation to venture into the field of philosophy of education, Greene faced considerable resistance from her male colleagues. In fact, she came to TC, so to speak, through the back door—through the editorship of *Teachers College Record* and the English Department, *not* philosophy of education. Evidently, her work was considered "too literary" for the field, an interpretation that she saw as code for "too feminine." Within a few years, however, she proved herself worthy of an appointment in TC's Department of Philosophy and Social Sciences, where she continued to teach well beyond her retirement. In fact, she offered courses in her Fifth Avenue apartment as recently as 2012.

Theoretical Contributions

Existentialism, literature, and the arts are the threads connecting Greene's intellectual project. After publishing *Existential Encounters for Teachers*, Greene developed her existentially informed philosophy of education in her groundbreaking book *Teacher as Stranger: Educational Philosophy for the Modern Age*. In this volume, Greene (1973) challenges the teacher "to *do* [italics added] philosophy" (p. 6). For Greene, when one "does philosophy," one is enacting and embodying a critical consciousness that examines the world in which we live, including educational processes, practices, and institutions. Implicit in Greene's concept of critical existential philosophy, derived from the work of Jean-Paul Sartre, is the commitment "to go beyond the situations one confronts and refuse reality as given in the name of a reality to be produced" (p. 7).

Refusing, going beyond, seeking wide-awakeness, choosing, and becoming are theoretical concepts and *actions* that inform Greene's signature contribution to the field of educational philosophy. Her unique imprint comes from her literary ability to embody these abstract concepts through references to literature, film, and other art forms. Honoring existentialism as well as John Dewey's pragmatism, Greene makes it possible for practitioners to understand her ideas as she makes meaningful connections to their own lives in classrooms. In fact, Greene is known worldwide for her lectures that subsequently become published essays. She can speak to teachers about lofty ideas, yet because these are grounded in lived experience, especially the lived experience of teachers and their students, these ideas tend to resonate powerfully with educational professionals. For example, her 1978 collection of lectures given between 1974 and 1977, *Landscapes of Learning*, addresses the concepts of *rationality*, *freedom*, *consciousness*, *wide-awakeness*, *praxis*, and *aesthetics* as they affect education and schooling. They are as relevant and accessible today, in the age of "No Child Left Behind" and "Race to the Top," as they were four decades ago when the back-to-basics movement dominated educational discourse.

One of Greene's most comprehensive books, *The Dialectic of Freedom* (1988), was an expansion of that year's John Dewey Lecture, presented at the meeting of the American Educational Research Association in New Orleans in April and, later that year, at TC. This book demonstrates Greene's intellectual reach as she brings into a coherent whole her mastery of critical, existential, and pragmatic philosophy together with history, multiculturalism, and the arts to show the complexities and contradictions of the American (educational) experience. Indebted to Dewey for an analysis of democracy and freedom, and for his commitment to the public good, Greene tells the stories of those who were thrust into the "underside of democracy." Her use of literature, film, and poetry to evoke the experiences of newcomers, freed slaves, and women is meant to show us the possibilities for freedom and community in a multicultural democracy.

Greene's work with the arts and education will perhaps be her most sustainable legacy. As the philosopher in residence for the Lincoln Center for the

Arts in Education for more than 30 years, Greene has offered public school teachers the educational and aesthetic theory, the artistic vocabulary, and the pedagogical skills to integrate meaningfully a range of cultural experiences in their classrooms. Greene's lectures and essays on education, the arts, and the social imagination have been collected in the volumes *Releasing the Imagination* (1995) and *Variations on a Blue Guitar* (2001).

It is her understanding and enactment of the *social* imagination that distinguishes her work from more traditional approaches to integrating the arts in education. For Greene (2001), the imagination can—and must—be employed in and for social contexts to "look at things as if they could be otherwise" (p. 122). Greene offers an invitation to *wide-awakeness*, to taking actions in situations that need changing. Hers is a philosophy of education intended for transformation—of our consciousness, our classrooms, and our communities. Her method of integrating the arts provides the openings and creates the spaces for *reimagining* the world without relying on dogmatic political ideologies or cultural stereotypes. Never too far from her roots in existentialism, Greene's work continues the search for meaning—for ways to connect our individual situatedness with and for the common good.

See Critical Theory

Habits

The notion of habit has had its ups and downs in the social sciences over the past 150 years. Its use as a key concept dates as far back as Aristotle, who connected it with education. In this entry, a definition of habit is offered, and its cultural mode of acquisition or inheritance is explained and contrasted with biologically inherited instincts. It is proposed that all reason depends on habit; and furthermore, it is a key component of some prominent definitions of culture. The concept is also important from an evolutionary perspective, for overcoming mind–body dualism and dealing with the agency–structure problem in social theory. Thus, the concept has great importance for social science and educational research.

The Concept of Habit

In *The Politics*, Aristotle wrote, "But in fact men are good and virtuous because of three things. These are nature, habit or training, reason." He continued, "education by habit-forming must precede education by reasoned instruction" (Book VII, chap. 13). Aristotle also noted pertinently in his *Metaphysics* that the word *habit* had two meanings: '"Habit' means a kind of activity" but in "another sense . . . 'habit' means a disposition" (Book V, chap. 20).

Confusion between the two meanings (behavior or disposition) persists today. Here, habit is defined as a culturally inherited disposition to engage in previously adopted or acquired behavior (including patterns of thought) that is triggered by an appropriate stimulus. It is "a more or less self-actuating disposition or tendency to engage in a previously adopted or acquired form of action" (Camic, 1986, p. 1044).

Habits are formed through repetition of action or thought. They are influenced by prior activity and have durable, self-sustaining qualities. Habits are the basis of both reflective and nonreflective behavior. They are economizers of scarce mental resources. If we had to deliberate fully on everything, then our reasoning would be paralyzed by the weight of data. Habits overcome this problem.

The concept of habit as a disposition was developed by a linked group of American pragmatist thinkers in philosophy, psychology, and economics. Among them, William James (1893) proclaimed, "Habit is thus the enormous fly-wheel of society, its most precious conservative agent" (p. 143). The institutional economist Thorstein Veblen (1898) wrote of "a coherent structure of propensities and habits which seeks realization and expression in an unfolding activity" (p. 390). As John Dewey (1922) put it, "The essence of habit is an acquired predisposition to *ways* or modes of response" (p. 42). A similar interpretation of habit as a disposition is found in the work of contemporary psychologists (Wood & Neal, 2007; Wood, Quinn, & Kashy, 2002).

Instinct, Habit, and Reason

By contrast, instincts are biologically inherited reflexes, feelings, or dispositions that can be triggered by specific cues. But (like habits) expressions of instincts can often be suppressed or diverted. There is clear evidence for some human instincts, such as reflexes in babies to clutch and suckle. It is beside the point to argue that acquired habit or socialization is much more important than instinct. But the importance of socialization does not deny the necessary role of instinct. Instincts are necessary for socialization to begin its work.

Brain imaging studies on human subjects show that the formation of habits involves a shift away from parts of the brain associated with conscious, declarative memory and goal setting (the medial temporal lobe and prefrontal cortex) toward areas associated with procedural memory and context-triggered responses (the basal ganglia).

Habits are vital to all thought and behavior. Rational deliberation relies on habits. In turn, instinct is prior to habit, habit is prior to belief, and belief is prior to reason. That is the order in which they have evolved in our human ancestry over millions of years. That too is the order in which they appear in the ontogenetic development of each human individual. That too is the order in which they are arranged in a hierarchy of functional dependence, where the operation of reason depends on belief, belief depends on habit, and habit depends on instinct. The lower elements are necessary but not sufficient for the higher.

As Charles Darwin noted, human rational capacities are built on subconscious mechanisms inherited from our prehuman ancestors. We retain instincts and unconscious mental processes that can function apart from our conscious reasoning. As some animal species developed more complex instincts, they eventually acquired the capacity to register reinforced behaviors through the evolution of mechanisms of habituation. In turn, on these mechanisms, humans built culture and language. Our layered mind, with its unconscious lower strata, maps our long evolution from less deliberative organisms. But when the human species evolved its capacity to reason, its dependence on instinct and habit did not decline.

Evolutionary Versus Mind-First Explanations

Much social science takes it for granted, or as true by definition, that "action" is motivated exclusively by reasons based on beliefs. This proposition is undermined by modern psychology as well as the evolutionary outlook offered by Darwinism. As noted by Benjamin Libet, experiments since the 1970s show that conscious sensations are reported about half a second after neural events, and unconscious brain processes are discernible before any conscious decision to act. This evidence suggests that our dispositions are triggered before our actions are rationalized: We contrive reasons for actions already under way. This apparently undermines explanations of human action wholly in the terms of reasons and beliefs.

But the folk psychology (Stich, 1983) that beliefs are the source of intentions, choices, and actions still dominates social science. These "mind-first" explanations of human behavior are unable to explain adequately phenomena such as sleep, memory, learning, mental illness, or the effects of chemicals or drugs on our perceptions or actions. Mind-first conceptions erect an unsustainable dualism or discontinuity between the mental and physical worlds, which is inconsistent with the fact of human evolution. Humans do act for reasons. But reasons and beliefs themselves are caused and have to be explained.

The habit-based perspective implies neither stasis nor lack of choice. As Dewey (1922) explained clearly, because of our engagement with diverse and changing contexts, we develop different habits of thought and action that sometimes come into conflict with one another. Such conflicts are opportunities for choice and change. Habit does not deny choice. On the contrary, the conflicting rigidities of different habits make choice inevitable.

Pragmatist and habit-based approaches overcome the Cartesian dualism of body and mind, which still pervades the social sciences. Intellect is not regarded as an independent and ungrounded causal power but as an emergent and active property of already-engaged dispositions and unfolding actions. The reality and importance of human intentionality and creativity is reconciled with the Darwinian evolutionary legacy and a philosophy of emergentist materialism (Bunge, 1980).

Conclusion

Once habit is seen as the foundation of preferences or beliefs, we can develop an enriched understanding of the interaction between individuals and institutions. Emergent institutions guide individual behavior. Individuals develop and reinforce habits consistent

with that behavior on which revised beliefs and preferences transpire. These revised beliefs or preferences lead to further actions and form more habits, which may affect institutions, and so on. This gives us two-way mechanisms of reconstitutive interaction from individuals to institutions and back to individuals.

The implications for social theory are profound, including a transcendence of the old debate between "bottom up" (methodological individualist) and "top down" (methodological collectivist) modes of explanation. In a full-fledged evolutionary view, causal influences have to be acknowledged in both directions. From an adequate evolutionary perspective, we have to understand how individuals are affected by social structures, as well as how structures are constituted by individuals. Habit is a crucial mechanism in both cases.

Happiness

What is happiness and why does it matter? What is the relationship between happiness and education? Should happiness be seen as a key educational aim, as some philosophers, teachers, and policymakers suggest? These questions are at the fore not only of much of philosophy and educational policy and practice but also of psychology, economics, sociology, neuroscience, and other domains. To resolve them may seem like an impossible task. "There is hardly a muddier concept [happiness] in the over 2000-year history of philosophy," says Kristjansson (2010, p. 300); Bruckner describes happiness as "an enigma, a permanent source of debates, a fluid that can take every form but which no form exhausts" (2010, p. 3). Watery metaphors abound, but progress can be made by reflecting on what happiness means to us as human beings and by clarifying basic concepts. This entry discusses various concepts of happiness, including the utilitarian concept of pleasure, the Aristotelian concept of flourishing or a good life, and the contemporary eudaimonic approaches. It then considers how a theory of happiness shapes our understanding of the goals and aims of education.

Two Concepts of Happiness

It is useful to start with the "original" concept. Children learn that happiness is an enjoyable experience that they want to prolong. It is contrasted with unhappiness, an experience they want to avoid, and subjective reports on both are normally taken seriously. If a child is lucky, her happiness is treated as a reason for action, though regrettably not (in all probability) an overriding one. In short, the original concept of happiness is hedonistic, polarized, subjective, and motivational. This concept underpins Jeremy Bentham's utilitarianism (1789), which sees happiness as pleasure, unhappiness as pain, and claims that these govern us in all we "do, say and think."

The original concept, often expressed as *feeling happy*, differs from the sense in which we say someone *is a happy person* or has *led a happy life*. The latter was important to ancient philosophers,

and Seneca (1932) expressed the problem well: "To live happily . . . is the desire of all people, but their minds are blinded to a clear vision of just what it is that makes a life happy" (p. 99). Happiness in this sense is something about which we learn by reflecting on our lives, our errors, and the limitations of the original concept. It is linked to Plato's idea of the examined life, and many philosophers (and more recently, positive psychologists) turn to Aristotle for guidance about its meaning.

The Aims of Education

According to Aristotle, eudaimonia (translated as happiness, well-being, flourishing, and a good life) is the ultimate end toward which we aim in whatever we do. In current idiom, it is a *thin specification* of this end, for its meaning is disputed. We generally agree that it is the most important thing in life; the philosophical task is to specify its meaning without, as Aristotle said, seeking more precision than "the subject matter admits of."

Aristotle is an objectivist; he never questions the scope for error in our thoughts about happiness. To thicken its specification is a task requiring reflective discipline, and Aristotle believed that "many" (the uneducated, the wicked, and the young) mistakenly characterize it as pleasure, honor, or wealth. The "wise" by contrast concur in the view that happiness means living and faring well. Living well means developing our distinctively human capacity for reason in moral and intellectual spheres; we cannot be happy without being virtuous or good. Thus, it would be wrong to infer (moving from the subjective to the objective perspective) that someone who gets away with her misdeeds and *feels* happy much of the time is a happy person.

There are no happy tyrants, on this view. Many people, preferring a subjective approach, would disagree, and here is a rich area of philosophical debate to which literature as well as argument may contribute much (Cigman, 2014). Most people nowadays also reject Aristotle's suggestion that happiness belongs within the framework of a complete life "or even beyond." Aristotle quotes Solon's "Call no man happy until he is dead" approvingly and adds (remarkably) that if misfortune befalls one's descendants after one's death, this will detract from the goodness of one's life as a whole. We may resist this thought, but the idea of embedding happiness in years or even decades, rather than moments or other brief periods, makes a certain sense.

We generally agree with Aristotle that a prerequisite of happiness is faring well. He sounds a note of realism (absent from the views of Plato and the Stoics) when he insists that the enjoyment of certain goods—reasonable health, modest wealth, and an adequate moral and general education—is important. Aristotle also resonates with modern intuitions by finding a role for happy *feelings* in the good life. The virtuous person, he says, takes pleasure in doing the right thing; although it is hard to be good, it is satisfying. This reinforces the idea (appealing to educators) that living virtuously is an aspect of living well.

This much seems clear: If happiness is to be an aim of education, we need a conception that is enriched by reflection and embedded in extended periods of time, if not an entire life. We want more for children than happy feelings and happy moments. Progressive educators such as A. S. Neill may have relied too heavily on the original concept, taking their cue from experiences that children enjoy and want to prolong and seeing these (too "precisely," in Aristotle's terms) as educationally motivational. Some philosophers of education have challenged these ideas; R. F. Dearden (1972/2010) argued that the "springs of action may be more complicated than a happiness-doctrine suspects" and "even anxiety can be facilitatory" (p. 82). Many teachers and parents would agree on this.

Scientific Approaches to Happiness

By identifying happy feelings as our governors in all we "do, say and think," and by introducing the idea of a "felicific calculus" that measures their intensity, duration, and other properties, Bentham provided a foundation for a psychology of happiness that many deem suitable for a scientific age (see Layard, 2005). The psychologist Daniel Kahneman's hedonic approach computes happiness in the Benthamite manner from a "dense record" of self-reported pleasurable and unpleasurable states. Positive psychology refines this, adding "life satisfaction" assessments and producing a composite conception of happiness (positive affect and life satisfaction) as subjective well-being. More recently, it has added a eudaimonic dimension, reflected in the title of Martin Seligman's 2011 book *Flourish*. Flourishing is Aristotle's objectivist concept, referring to the fulfillment of natural capacities. Human flourishing, unlike that of a tree or dog, involves virtue, and positive psychologists claim that they can measure this. *Can* virtue be measured? It is a

controversial question on which many philosophers have expressed doubts.

Subjective and objective approaches to happiness have been amply criticized. Few nowadays see happiness as synonymous with pleasure, for a life that ranks highly on a hedonic scale may be utterly pointless. Robert Nozick's "experience machine" thought experiment highlights the undesirability of a condition in which neurological stimulation (the notorious "brain in a vat") might create the *illusion* of a flourishing life. Few would be tempted by the prospect of limitless pleasure if the distinction between reality and illusion were entirely lost. Life satisfaction seems closer to what we mean when we call people happy, until we reflect that some are satisfied with limited or impoverished lives because they are ignorant, self-effacing, or oppressed. Eudaimonic accounts appear to resolve these difficulties, but many regard the idea of *contesting* a person's subjective sense of happiness, on the authority of science or philosophy, as unacceptably paternalistic.

Eudaimonic accounts have, at least, this to recommend them: They recognize that not all kinds of happiness are equally worth having. Criticizing Bentham, J. S. Mill insisted on this point when he argued that some pleasures are "higher" than others. It is better to be Socrates dissatisfied, he said, than a pig satisfied, as any competent judge who knows both will attest. This complicates the quantitative model, for "higher value" is hard, if not impossible, to compute.

Mill's competent judges are problematic. Any attempt to identify them would be infinitely regressive, and the elitist implications are offensive. This is, however, a pivotal moment for contemporary philosophizing about happiness. Like Aristotle, Mill understood that happy and unhappy feelings are not simply experienced; they are also evaluated, reflected on, and "learned about." Sometimes, as Friedrich Nietzsche emphasized, it is good to feel unhappy, and Peter Roberts (2012, p. 209) argues in this vein that suffering has "profound value for our development as human beings" and that education "should make us uncomfortable." If there are "higher pleasures," there are presumably "higher pains," and education could be a rich site for both.

Implications for Educational Theory and Practice

Education is an ethical practice, needing what Avishai Margalit (2002) calls a "literary picture": "We are the authors of our lives, and we had better make sure that they add up to something meaningful" (p. 134). It is arguable that recent educational policy has neglected this picture. The enhancement agenda (social and emotional learning, happiness lessons) tends to polarize positive and negative feelings, promoting the former and trying to inhibit the latter (Cigman, 2009). It asks "how children are" and returns gloomy statistical answers, aiming to reverse these through national interventions (Department for Education and Skills, 2005; Seligman, Randall, Gilham, Reivich, & Linkins, 2009). It is strongly influenced in the United Kingdom by Richard Layard's Benthamite philosophy; happiness ("feeling good"), says Layard, *can* and *should* be learned early in life. Pascal Bruckner (2010) describes this as a perversion of the Enlightenment's "beautiful idea: that everyone has the right to control his own destiny and to improve his own life" (p. 5). Is he right? Is there now a *duty* to be happy, intrusively pursued through education? Many believe this to be the case, and the need to reflect on such questions could not be clearer. Instead of drowning in watery metaphors, this entry aims to provide a rudimentary map.

Hegel, Georg Wilhelm Friedrich

Few thinkers in the history of Western philosophy are as important or as contested as G. W. F. Hegel (1770–1831). Slavoj Žižek has argued that there is a unique philosophical moment in the West in which philosophy first appears in-and-for-itself, or in which it rises to its own self-consciousness. This is delineated by Immanuel Kant's *Critique of Pure Reason* (1968) and Hegel's death (1831); philosophy before and after this, he says, is only preparation and interpretation, respectively. Hegel taught both in schools and in universities while writing his two great works, the *Phenomenology of Spirit* and the *Science of Logic*; many of his other books consist of lectures given at the University of Berlin between 1818 and 1831. The range of Hegel's work—across aesthetics, law, religion, the state, logic, epistemology, and metaphysics—and the abstract, difficult, and sometimes apparently paradoxical nature of his prose make conducting a short survey precarious.

Since his death, at least two schools of interpretation have sprung forth: *Right-wing Hegelianism* has followed through with Hegel's claim to have realized the absolute, or absolute truth, in the form of a broadly Christian philosophy; while *left-wing Hegelianism*, to which the young Karl Marx subscribed, absorbed Hegel's dialectical critique of modern civil or bourgeois society. Two French thinkers in particular, Alexandre Kojève and Jean Hyppolite, reintroduced the *Phenomenology* into the existential climate of France in the 1930s and beyond. Foucault, Deleuze, and Derrida, among others who were to be influential in the closing decades of the 20th century, were taught by Hyppolite.

Hegel and the End-of-History Thesis

One topic within educational theorizing above all others implicates Hegel as a theorist of a largely discredited notion of modernity. The now infamous "end of history" thesis, as discussed most recently by Francis Fukuyama, argues that Western liberal democracies are the endpoint to which history has always been leading. Fukuyama states that Kojève in particular claimed somewhat intransigently that history has ended, or is coming to an end, and that observing it is now clear that the future belongs not to the exploitative master in the world but to the working slave. Both Kojève and Fukuyama lean heavily on Hegel's idea of mutual recognition (from the *Phenomenology*), where all persons recognize themselves as identifying each other (such mutual recognition is seen by some to offer a model for the homogenization of human freedom across the world). Kojève also highlighted the seemingly counterintuitive claim, found in Hegel's analysis of the master–slave relationship in the *Phenomenology*, that the master is really the slave because of his dependence on the slave, and the slave is somehow a master because he is true to himself; the implication is that the slave is potentially freer than the master. In a world where masters and slaves remain, Hegel's study is still relevant, offering a powerful philosophical template for the critique of one-sided authority and power wherever it appears (including that between teacher and student).

The association of Hegel with the end-of-history thesis has encouraged many theorists in education and elsewhere to see Hegel as the archetypal modern, Western, White, male, rationalist representative of the imperialist view that "West is best." There is ample evidence in Hegel to support them, ranging from his work on the modern state, to his description of women as plants, and of Negroes as a race of children immersed in a state of uninterested naiveté. But as Hegel realized, those who condemn as an imperialist master any thinker who assumes a position of authority over those deemed less enlightened are repeating precisely that which is being condemned. It is also the case that Hegel understood his own complicity within the dominant social relations of 19th-century Europe, and he explicitly described not only how his own work carried the shape of those relations but also how his work would be interpreted as if it had overcome such complicity—which it had not.

The Dialectics and the *Aufhebung*

It is well known that at the heart of Hegel's philosophical system lies a triune model of human experience or consciousness. Ordinary consciousness accepts a taken-for-granted reality; dialectical consciousness questions and negates that reality; and

philosophical consciousness comprehends the whole of this experience. Few educators would want to oppose a critical consciousness. The controversy in Hegel then is the relationship between critical dialectical consciousness and philosophical consciousness. If dialectics negates our taken-for-granted view of the world, it can be destructive, even violent, for it pulls the rug out from under our feet. It robs us of the certainties which held our world together without seemingly putting anything back in their place. We are left looking down at a gaping abyss where the certainties of life have disappeared.

The key controversy in Hegel begins at this point. How, if at all, does he protect us from this abyss? Right-wing Hegelians call on the religious absolute, and left-wing Hegelians on the value of the critical consciousness in itself. But both camps need to engage with the Hegelian concept that addresses the abyss and which holds all of Hegel's philosophy together, namely, the *Aufhebung*. Seeking help in a dictionary here is not fruitful. The dictionary will tell us that the verb *aufheben* means to abolish, to raise up, and to preserve, while *Aufhebung* describes this process. But abolishing, raising up, and preserving seem to contradict one another. Understanding what Hegel makes of this contradiction is the most important step in appreciating his whole philosophy.

One can approach this issue in many ways, but here are two. First, when we learn something, it is said that we leave behind previous thinking and move on to new thoughts. The new thinking overcomes the old, and the new provisional truth overcomes the old defunct error. This assumption of overcoming error is carried in the idea of *enlightenment*. But overcoming error suggests that it does not also preserve error, and preservation is part of what the *Aufhebung* demands. It is in *philosophical experience as learning* that the *Aufhebung* carries all three meanings of abolish, raise up, and preserve. This is because learning about philosophical experience as an experience of philosophical learning has a unique significance. When learning learns about itself—something Aristotle ruled out in the *Metaphysics*—it overcomes itself and preserves itself. Learning changes and remains itself in doing so. Understood in this way, the *Aufhebung* is fundamentally an educational concept, and it announces Hegel's philosophy as a distinctive, seminal modern philosophy of education.

Second, one might agree that the *Aufhebung* is a continuing experience of learning but still question how Hegel would describe *Aufhebung* as in any sense *absolute*. What we have to realize is that Hegel is trying to reeducate us about how we should understand the very idea of truth. Following Socrates's lead more than 2,000 years earlier, Hegel holds that contradiction—for example, that between abolishing and preserving—far from being a sign of error, is really a sign of truth. This is where analytical philosophy and Continental philosophy part company. Analytical philosophy regards contradiction as indicating error, whereas Hegel finds contradiction to be truthful when it reflects the difficult relationship that thoughts have to their objects. This is what makes Hegel so difficult to read, because his logic is deliberately contradictory; but at the same time, it is absolutely rigorously contradictory—contradiction is the rational and spiritual basis of his whole science of logic.

To put this in another way, for Hegel, thought cannot understand the concept of truth without thought getting in the way, or in Hegelian language, thought inescapably *mediates* everything it thinks, including truth. Here, reason threatens to slide down the slope of infinite regress, unable to resist mediation ad infinitum; this leaves us with something similar to what Max Horkheimer and Theodor Adorno called the *dialectic of enlightenment*. So the crucial question here is this: Does mediation mean that thought prevents us from ever knowing the truth, or does it make it possible? More philosophically, is there truth in itself, or is truth in itself always unavoidably just truth for us who think about it? More colloquially, is truth objective or subjective?

Hegel's answer to this question is as simple as it is powerful and can be illustrated with the following example. Allan Bloom said in 1987 that the one thing every university tutor could be sure of was that most students will believe that truth is relative and not absolute. Absolutism is a dogma with colonialist, imperialist, gendered, racist, and much other cultural baggage. One should not force one's truth down someone else's throat. Indeed, Hegel says as much in the shorter *Logic* (§23), stating that no one can think for another person any more than one can eat or drink for another. Hegel's response to this challenge of absolutism is direct. How does a student know so much about what truth is, to be able to know so definitively what it is not? To say that mediation is *not* true involves the prejudgment that one knows what truth is. So does this leave one with or without truth? Here, Hegel asks only for integrity in the face of the dilemma. If negation (or mediation) is ubiquitous and unavoidable, if it is universal,

then perhaps this makes a better claim for truth than any of one's presuppositions about what truth is or is not. The upshot is that for Hegel, universality lies in the thinking, or mediation, of truth.

But even if this is so, what difference does this really make to life as we live it? Is such thinking not exactly the kind of scholastic rarefied knowledge that the humanists so lamented in the Renaissance? How can one bring such philosophy down to earth? For Hegel, the problem is the opposite. In the *Phenomenology* (§8), he suggests that there was a time when the gaze of the Western individual needed to be brought down to earth, but presently, the need is the opposite: to raise our impoverished spirit back to something more than the worldly things that demand our attention. Few Western philosophers have put the truth of such a difficult education so firmly at the center of their whole philosophy as Hegel has done.

Influence on Education Theory

How is Hegel currently shaping educational debates? Much recent educational theory is "post-foundational." This means that it holds to a pluralism of values and truths above any dogmatic claims for grand narratives or overarching ideas that are timeless and universal. This perspective tends to see Hegel as representing totality and absolutism over openness and relativity. A notable exception is the reading given by Žižek, which finds Hegel never closing down or resolving thinking in anything that could be final. Indeed, Žižek's Hegel holds that even the self is never transparent to itself and always evades capture by the understanding. For Žižek (and for the author of this entry), the postfoundational readings that see totalitarianism in Hegel fail to take account of the contingency—the lack of ground—that Hegel understands he is condemned to work with by the times in which he lived and in particular by dominant social relations. It is the case that in Hegel, the absolute is always trying to reeducate us philosophically about the subjective nature of absolute truth and the absolute nature of subjective truth, a contradiction which Hegel and the absolute refuse to abandon.

Educational theory that is broadly Marxist, including the Frankfurt School of Critical Theory, has largely ignored the significance of the Hegelian absolute for fear of being associated with the right-wing Hegelianism of absolute spirit. At best, they are content to decapitate the absolute or the *Aufhebung* from the dialectic, and while this leaves a very powerful tool for social and political critique, from Hegel's point of view, it treats as optional the significance that dialectical thinking has for itself.

In addition, Hegel's philosophy gets mentioned in relation to the educational theory of *Bildung*, but often only one sidedly. It is true that Hegel saw *Bildung* as an education for learning the value of service to the objective spirit of the state. But the key here again is what is meant by learning. *Bildung* in Hegel is the representation of philosophical learning as a "culture." Culture in Hegel is the sphere of everyday life where we live out the many different ways in which we are exposed to the contradictions of the *Aufhebung*; for example, where openness opposes absolutism, where the subjective opposes the objective, or where man contradicts God. Everything that involves a human being trying to represent himself or herself within or without truth is a culture; and it is a culture, in Hegel's sense, precisely because this is the site of the contestation between truth and nontruth. Hegel's notion of culture offers educational thinkers and practitioners a concept of their own work, their own struggles, difficulties, and contradictions, as the lived truth of their own learning.

What of the future for Hegelian philosophy and educational theory and practice? Žižek has argued that Hegel, as the philosopher of modernity, remains the most relevant thinker in responding to the troubled times afflicting modern Western-style capitalism on a global scale. But seeking a return to Hegel here is ambiguous because in effect modernity has never left Hegel. His philosophy remains the template for trying to grapple with its contradictions. The many still-influential standpoints of postfoundationalism show signs of their own exhaustion; in feminism and in postcolonial studies, the dialectic of enlightenment is emerging in which the champions of the oppressed are gloomily forced to account for the mastery of their own standpoint. Here is the culture of the post-men and post-women; a culture that is already Hegelian. There is no telling how this dialectic of enlightenment will be comprehended within the cultures of cultural studies, but Hegel stands ready to help in comprehending these unavoidable aporias (puzzles that lead to incompatible or conflicting resolutions) as philosophical experiences of human learning. If such truthful learning is comprehended as an end in and for itself, so be it. If not, culture will continue to eschew its own educational significance.

Hegel will also continue to haunt discussions about God and freedom. Just as God returned to Zarathustra in Book IV of Nietzsche's tale, so God returns to modernity in the broken freedoms of Western society. One of Hegel's most challenging thoughts is that the idea of God and the idea of freedom share the same origin in social relations. Religion in Hegel is the way people represent to themselves their lack of freedom. So the Christian God is the representation of one's subjectivity in relation to the universal, reflecting the lack of unity between them and the obstacles to any mending of this brokenness.

Finally, there remains the thorny issue in Hegel of world spirit. Since the Stoics in antiquity, the idea of cosmopolitanism has held the imagination of many thinkers—of a world which is united, embracing fundamental human principles of justice and peace. But such a vision has itself been criticized as a form of imperialism, in that cosmopolitanism is really only Western ideals pushed across the globe. Hegel's notion of world spirit is seen by some to be the most pernicious example of this imperialism. It *is* the case that global capitalism has produced a world spirit—but reading Hegel carefully can open up, not close down, ways of criticizing just this kind of imperialism.

As long as modern educational theory is shaped by the social relations of private property, Hegel's critique of the universality of such relations, and of the complicity of life and thought within them, will continue to be relevant and vital.

Heidegger, Martin

Martin Heidegger (1889–1976), a German philosopher, is best known for his writings on phenomenological ontology, which provided a revolutionary account of human existence and the history of metaphysics, which he provocatively called "the history that we are." Even though Heidegger never formally developed a philosophy of education, it is not wrong to say that he had two of them. The first relates to what I will refer to as "the task of selfhood," which Heidegger develops in his 1927 magnum opus *Being and Time*. The second relates to what this entry will refer to as "ontological education," which he develops in a variety of writings from his later philosophy, but especially in his 1940 essay "Plato's Doctrine of Truth" and his 1951–1952 lecture course *What Is Called Thinking?* In both cases, Heidegger understands education to involve (1) turning away from the everyday world, (2) undergoing a transformative experience of liberation and self-recovery, and (3) returning reflexively to the everyday (one's projects, roles, and the entities of one's environment) with a new understanding of oneself and one's world.

Genuine education for Heidegger (1998c) is always emancipatory. As he says in his famous essay on Plato's cave allegory, "Real education lays hold of the soul itself and transforms it in its entirety by first of all leading us to the place of our essential Being and accustoming us to it" (p. 167). This transformative return to the self, in both of Heidegger's philosophies of education, involves the liberation of oneself

from forces of resistance. In the task of selfhood, resistance comes from "the they" (*das Man*), which encourages conformity and discourages individuality. And in ontological education, resistance comes from the metaphysics of one's age, which shapes our thinking so profoundly that we cannot help but see everything, ourselves included, as resources awaiting optimization. We see nature, for example, as little more than "a giant gasoline station" (Heidegger, 1966, p. 50).

The task of selfhood in *Being and Time* is designed to awaken us from the tranquil but inauthentic lives we lead under the influence of *das Man* and to reconnect us to the everyday world of our concerns with a new appreciation for our freedom and a resolute acceptance of the existential responsibility it entails. This kind of education reacquaints us with ourselves as finite, self-creating beings. In contrast, the purpose of ontological education in Heidegger's later writings is to help us leap over the wall of metaphysics and overcome nihilism. This second kind of education reacquaints us with ourselves as world-disclosing beings and accustoms us to a world that is conceptually inexhaustible, fundamentally mysterious, and aglow with "divine radiance." Ontological education, then, like the task of selfhood, culminates in an enlightened recovery of one's Being and the Being of the world. Its aim is nothing less than the reenchantment of the earth.

The purpose of this entry is to explain the details of these separate but related ideas about the essence of education.

The Task of Selfhood

Heidegger's philosophy of education in *Being and Time* is best understood as a special kind of philosophical perfectionism, the conceptual foundations of which derive from Aristotle. In *Being and Time*, Heidegger provides an account of (a) what makes human beings distinctive among beings, (b) what it means for humans to flourish, and (c) how human flourishing, what Aristotle called *eudaimonia*, is a product of becoming what one is in spite of the contrary education one receives from *das Man*.

What makes us distinctive, Heidegger (1962) says, is that our Being is an issue for us. "*Dasein* [the human being] is ontically distinctive in that it *is* ontological" (p. 32). We are unique among beings because we have an understanding of being, and because, for us, Being is an issue. It is both (a) a constant source of wonder—we ask why there is anything at all instead of nothing—and (b) a task—being human requires that each one of us makes self-creating choices. For Heidegger, we *are* what we choose. We don't just exist, like rocks and plants; we aren't simply given an essence. We are choosing beings, stretched through time, open to a past and a future, and always faced with the task of selfhood. Who we are is who we are not yet (p. 287). "The most primordial and ultimately positive way in which Dasein is characterized ontologically" (p. 183) is as "being-possible" (*Möglichsein*).

This is what Heidegger means when he says we *are* ontological. We don't exclusively understand Being from the theoretical point of view, as the philosophical tradition has always supposed. We also *embody* an understanding of Being and literally live answers to our questions about the sorts of people we ought to be. Sometimes, we live those answers consciously and deliberately; other times—more often, Heidegger would say—we make world-shaping, self-creating choices without thinking freely about our possibilities and taking ownership of ourselves. To be human is to take a stance on who and what we are (Am I a teacher or a lawyer, a husband or a single man?) and to be defined and shaped by that stance. The key question is whether (a) we define ourselves consciously, deliberately, and with a passionate commitment rooted in a profound confrontation with our mortality, or (b) we are simply doing what one does and, as if sedated, going with the flow of life: believing what "they" believe, living as "they" live, and valuing what "they" value.

Two pieces of Heidegger's philosophical perfectionism should be relatively clear at this point. First, we are ontically distinctive because we are ontological: For us, Being is a task that involves choices, as well as a source of wonder that demands reflection. Second, we can make our self-creating choices consciously or unconsciously. If we make them unconsciously and live according to ideas that are not our own, we fail to become authentic selves. We don't really take up the task of selfhood but, instead, flee from it. Heidegger (1962) calls this kind of failure "falling" (p. 219), and he suggests that it characterizes most of us most of the time: "Everyone is the other, and no one is himself" (p. 165). On the other hand, if we choose consciously between the possibilities open to us, and independently of the tyranny of custom, we can complete the task of selfhood and fully become what we are. Heidegger calls this relationship with our possibilities authenticity, and he intends for us to see that it is the *practical* fulfillment of our being.

Aristotle's moral perfectionism tells us that human beings are distinctive because they are rational and that flourishing consists in reasoning well, especially in the context of theory (*Nichomachean Ethics*, Book I, chap. 8). Heidegger's (1962) development of this idea is to say that we are distinctive theoretically *and* practically. On the one hand, he agrees that human beings are perfected, or fulfilled as what we are, through philosophy (pp. 33, 96). But on the other hand, we are also fulfilled practically, that is, through a kind of choice making that is done in the light of death, and done resolutely. "Dasein becomes 'essentially' Dasein in that authentic existence which constitutes itself as anticipatory resoluteness" (p. 370). Anything short of authenticity, on this view, is a failure to flourish because it doesn't involve making free choices or overcoming "the dictatorship of the one [*das Man*]" (p. 165).

For Aristotle, human flourishing is characterized by reasoning well. For Heidegger, human flourishing is partly constituted by completing the task of selfhood in light of one's mortality. Death makes us anxious, and anxiety (*Angst*) is transformative and liberating because it is illuminating. In *Being and Time*, Heidegger is careful to distinguish *Angst*, which is about the burden of living a human life, from the kind of anxiety that we feel over an upcoming test or a difficult conversation. *Angst* is more rare and more profound than these everyday forms of anxiety. We feel it when our worlds collapse, that is, when our projects and roles—all of the things that shape our identities—no longer seem to matter. In these moments, it is as if the ground has dropped out from beneath our feet. The world we had taken for granted, the world of our everyday concerns, slips away from us. Suddenly, the familiar seems unfamiliar, and the ordinary feels uncanny.

In these moments, we continue to exist as "being possible." We go on projecting ourselves into an open future, but we project ourselves on a world and into an identity in which we no longer feel at home. Heidegger (1962) calls this experience "death" (p. 307), and he suggests that through it we encounter the structure of our being. We realize, in a practical way, that we are self-creating beings who enjoy meaning and value as a by-product of our choices, and in proportion to the passion we invest in them.

> With Dasein's lostness in the one . . . Dasein makes no choices, gets carried along by the nobody, and thus ensnares itself in inauthenticy. This process can be reversed only if Dasein specifically brings itself back from its lostness in the one. . . . When Dasein thus brings itself back from the one, the one-self is modified in an existential manner so that it becomes authentic being-one's-self. This must be accomplished by making up for not choosing. But "making up" for not choosing signifies choosing to make this choice, deciding for an ability-to-be, and making this decision from one's own self. In choosing to make this choice, Dasein *makes possible*, first and foremost, its authentic ability-to-be. (p. 312)

Death clarifies our lives for us, allowing us to distinguish between what is trivial and unimportant and what has lasting significance. We return to ourselves from *das Man* with a new appreciation for our freedom and a new ability to embrace and own the task of selfhood.

This experience of existential death and rebirth constitutes a form of education because it "lays hold of the soul itself and transforms it in its entirety by first of all leading us to the place of our essential Being and accustoming us to it" (Heidegger, 1998c, p. 167). In fact, it is hard to imagine how anything else could fit this description of "real education" (Heidegger, 1998c, p. 167) any better: We lose the world in death, rediscover ourselves in resoluteness, and then freely return to our projects with a new capacity for ownership of who and what we are. We are transformed in the process and led back to the place of our "essential being." We are led back to and given an opportunity to repossess ourselves.

Ontological Education

Heidegger's second philosophy of education also involves a transformative return to the self, although in a very different way from the task of selfhood in *Being and Time*. It is easiest to see this by thinking about Heidegger in connection with Nietzsche, who once said famously that the role of the philosopher is to be "a gadfly on the neck of man" and act as humanity's "physician." This medical metaphor applies to many of modernity's most influential thinkers—for example, G. W. F. Hegel and Karl Marx, Søren Kierkegaard and Friedrich Nietzsche, Rainer Maria Rilke, Sigmund Freud, Franz Kafka, and the Frankfurt school thinkers—who diagnosed the modern world with a cultural or spiritual "sickness" and presented their own philosophies as a corrective therapy. Heidegger's "later philosophy" can be understood as fitting into this tradition. Modernity, he says, is the age of the "world's night."

It is an era of destitution and decline. The function of his "ontological education" is to help us recognize the symptoms and causes of our condition and to provide us with a therapeutic philosophy that can heal us.

What is revolutionary about Heidegger's critique of modernity is the role he assigns to *metaphysics* in causing the most pressing problems of our time: "the loss of the gods" (the disenchantment of the earth), homelessness (the devaluation of the highest values), and the "violence" of modern technology (environmental degradation, factory farming, vulture capitalism, sweatshop labor, wars for oil, etc.). Heidegger explains these "symptoms" as products of our metaphysical thinking about Being, which mistakes *one* way of disclosing reality for *the* structure of reality itself, and so misses "the truth of Being." We will heal ourselves from the affliction of our age, Heidegger (2003) argues, only if we manage to overcome metaphysics (p. 67) and relate to our world and to ourselves without being blinded by the reifying categories of what he calls "ontotheology," which we experience as "enframing." But what exactly is ontotheology, and why is it a problem?

An ontotheology is any attempt to think about Being ontologically and theologically at the same time (Heidegger, 1998b, p. 340). We think about Being ontologically when we try to understand the most basic "stuff" that makes entities what they are. The pre-Socratic philosopher Thales (ca. 624 to ca. 546 BCE) thought it was Water. Plato thought it was Forms. Nietzsche thought it was the Will to Power. On the other hand, we think about Being theologically any time we try to understand reality from a God's eye point of view; that is, from what Thomas Nagel calls "a view from nowhere," so that we can grasp the structure of the whole and the way entities exist: how they are arranged with respect to each other, how they came to be, and whether they are organized by laws or purposes.

Anaximander (ca. 610 to ca. 546 BCE) was the first "theological" thinker, then, because he speculated that the universe was governed by a cycle of opposites. Plato's forms divided Being into degrees of reality, so that entities are more or less beautiful, more or less good, more or less just, etc. Aristotle's hylomorphism provided the West with its first robust ontotheology, which modern science has replaced with an ontotheology of its own, nonteleological naturalism, the details of which undergo periodic changes as science makes progress, but whose ontotheological structure is unchanging.

> Metaphysics represents the beingness of beings in a twofold manner: in the first place, the totality of beings as such with an eye to their most universal traits . . . but at the same time also the totality of beings as such. (Heidegger, 1998a, p. 287)

In passages like this, Heidegger wants to underscore that *as ontology* metaphysics asks what entities are in general and what entities share in common. And *as theology*, it attempts to identify and define the nature of the whole (for Hegel, God is the whole structure of beings, not an individual entity), which it sometimes, though certainly not always, considers divine (Nietzsche's atheistic "theology" is Eternal Recurrence). Ontotheology, then, is the interior structure of our theories about Being.

The problem with ontotheology is that Being is conceptually inexhaustible. It always exceeds the categories we use for understanding it, and so it is not reducible to the Being of entities. This means that *any* ontotheology, whether ancient or modern, is an incomplete and partial representation of Being, which is *both* what is revealed to us by our ontotheological categories and what is ineluctably concealed by them. In fact, any understanding of Being is incomplete and *incomplete-able*. And yet every ontotheology tries to provide closure on the question of Being, focusing exclusively on the Being of entities. Every ontotheology is therefore forgetful of Being as such. For example, as long as Being appears to us as an intelligently designed, good, and teleologically ordered creation of God, it is concealed as Eternally Recurring Will to Power, and vice versa. Even a metaphysical theory like Plato's, which posits a Good "beyond being," nevertheless treats the Good as a special kind of entity, and so remains ontotheological.

One might be tempted to think that this is all very academic and that it has no bearing on life as ordinary people live it. But Heidegger insists that ontotheology always *matters* because it "grounds an age" (Heidegger, 1993, p. 115) by serving as the "lenses" through which we understand the world and ourselves. In fact, we embody, individually and collectively, the understanding of Being articulated by the ontotheology of our time.

Our own age is nihilistic because our ontotheology (Heidegger thinks it is Nietzsche's picture of Being as Eternally Recurring Will to Power) has disenchanted the world and thereby reduced Being to "a vapor" (Heidegger, 2000, p. 42), the meaningless aggregation and disaggregation of forces. That is how we see the world, deep down. That is how *we*

understand Being. For evidence, Heidegger would simply have us look at the way we live, how we treat one another and ourselves, how we treat the earth, and how we think. We understand everything as lacking intrinsic value. For us, Being is a storehouse of resources, what Heidegger calls "standing reserve" (Heidegger, 1993, p. 23). The world revealed to us as mere resources is what Heidegger means by "enframing," and enframing (*das Gestell*) is the common thread linking the excesses of cosmetic surgery and the plundering of the earth, the neuropharmacology boom and the rise of vulture capitalism, etc. Each of these social and political problems has a common ontotheological root.

The purpose of ontological education is to enable a relationship with the world that happens outside the confines of ontotheological thinking. Heidegger's (1966) goal, in turning to art and poetry in his later philosophy, is to remove the "lenses" of ontotheology and replace them with a receptive openness to the forgotten but inexhaustible effulgence of Being. Heidegger calls this postmetaphysical relationship with the world "openness to the mystery" (pp. 12, 21, 55, 56, 92), and his hope is for us to relearn "to dwell" in the world and to cultivate an open relationship with Being, one that lets entities be what they are by constantly freeing them to be more than what they have been.

Like the task of selfhood in *Being and Time*, ontological education involves (a) turning away from the everyday world (in which entities show up as resources), (b) a transformative experience of liberation (from the reifying confines of ontotheology) and self-recovery (as beings who are in a dynamic, world-disclosing relationship with a mysterious, conceptually inexhaustible reality), and (c) a reflexive return to the everyday that is characterized by receptivity and openness to the unbidden rather than mastery and control.

Both in the task of selfhood and in ontological education, real learning occurs when the student returns to the place where she started and got to know it for the first time.

Herbart, Johann F.

Johann Friedrich Herbart (1776–1841), a German philosopher and a student of philosopher Johann Gottlieb Fichte, is considered a foundational figure in the history of educational philosophy. Over the past two centuries, since the time of his major work on education *The Science of Education* (*Allgemeine Pädagogik*; 1806), his thinking has had a profound influence on educational philosophy and educational reform worldwide. This entry thematizes three central components of Herbart's philosophy of education: his twofold concept of education and its connection to his practical philosophy; his concept of perfectibility; and his notion of pedagogical tact, especially as it relates to teacher education.

Concept of Education

Herbart's concept of education draws out the moral meaning of education. For Herbart, education aims toward the self-determination (*Selbstbestimmung*) of the learner. His notion of self-determination refers to the ability to critique one's own self-interested ideas and motives for action, as well as the values and norms that govern society. The concept of a person who is self-determined, or autonomous, is not to be conceived of as one who is individualistic and lacking a connection to the social world. Rather, self-determination for Herbart connects directly to one's ability to make moral judgments, judgments that reflect one's recognition of others. As Herbart (1804) puts it in his influential essay "The Aesthetic Revelation of the World," morality is not simply the highest but the *whole* purpose of education.

From a historical perspective, Herbart's concept of education opposed notions of education of the *ancien régime*, which assumes that the next generation's future is decided by the previous generation, that is, by tradition and socialization. On Herbart's model, it is not the role of education to guide learners into an existing moral order or make them dependent on external authority.

For Herbart, the categorical imperative formulated by Immanuel Kant (1724–1804) is central to understanding morality. The categorical imperative expresses a judgment of oneself according to principles of universality and humanity. It thus captures for Herbart what it means to judge oneself in light of one's recognition of and respect for others. But, going more in depth than Kant, Herbart asks the question of how the educator can help a learner learn how to make judgments for himself or herself about what is good and right to do in a given situation.

Herbart's answer to this question is not a learner-centered model, where the teacher is a mere observer, nor is it a teacher-centered transmission model. Rather, he develops a concept of education that accounts for a certain kind of intersubjective relationship between teacher and learner, which he sees as essential for cultivating the learner's ability to think, make independent judgments, and become what he terms a *multifaceted individual*. A multifaceted individual is someone who is interested in the differing perspectives, new ideas, and new objects that he or she encounters.

Herbart develops a twofold concept of what he calls "education proper" that outlines the educator's task in educating another person. The educator's task is defined using two terms: *educative instruction* and *moral guidance*. The first term, educative instruction (*erziehender Unterricht*), describes the educator's task in cultivating the learner's knowledge and ability. For Herbart, instruction has the aim of introducing learners to multifaceted forms of knowledge and human interaction, so that learners can understand differing perspectives and expand their interests beyond the confines of everyday life. Herbart thus conceptualizes the learner's path as a

series of stages according to the principles of a theory of association. In turn, the educator's task is to support the learner to steadily and continuously associate known objects with closely related new objects and then reflect on the process of making these new associations. Herbart's followers, the Herbartians, simplified and standardized this method of teaching, which came to be widely known outside of Germany, including in the United States, as the "Herbartian steps."

The second term, *moral guidance*, describes the educator's role in supporting the learner's moral development. Herbart's term for moral guidance is "*Zucht*," which comes from the German verb "*ziehen*," meaning *to pull forth*, and is associated with the latin "*educare*." Moral guidance should not be understood as discipline (even though the term *Zucht* is often translated as *discipline*). Although Herbart identifies a need for discipline (*Regierung*), he defines discipline as confined to the task of preventing the learner from harming himself or herself, or others. Thus, discipline is a precondition for, but not part of, education proper.

Moral guidance, for Herbart, describes a form of dialogic interaction with the learner to help him or her critically examine self-interested inclinations and judge these according to moral ideas. A central aim of such dialogue is to help the learner develop an "inner censor." The inner censor comes forth in moral dilemmas when we ask ourselves the question, What should I do? The inner censor can be construed as an individual's inner self-critical voice telling the individual what not to do, much like Socrates's *daemon*.

A key concept associated with how educators should cultivate a learner's inner censor is found in Herbart's notion of "inner struggle." Inner struggle arises when we attempt to confront past decisions and make changes in the way we think and act in the world. Herbart's notion of moral guidance underscores that the educator must not attempt to alleviate the learner's own inner struggle, for example, by telling him or her what to do. Rather, in his view, the educator must support learners to engage in inner struggle, question their past decisions, and inquire into how to make choices that respect others.

The aim of moral education is to develop a disposition in the learner to judge situations of action reflectively, not normatively. Herbart (1808) connects his theory of education directly to his ethics, expounded in his *General Practical Philosophy (Allgemeine Praktische Philosophy)*. Expanding on the idea of the Good Will expressed in Kant's categorical imperative, Herbart delineates five individual moral ideas to which he imparts specialized philosophical meanings: (1) *inner freedom* (*innere Freiheit*) captures the need for critique of one's will in all judgments of what to do; (2) *completeness* (*Vollkommenheit*) addresses the need to have differing perspectives to inform one's view; (3) *benevolence* (*Wohlwollen*) captures the need to express good will toward imagined others; (4) *right* (*Recht*) expresses the need to find agreements in cases of conflict with others; and (5) *justice* (*Billigkeit*) addresses the need to correct broken agreements and compensate those adversely affected. The moral ideas represent aesthetic relations of the will that are meant to orient one's view of oneself in relation to one's will, to objects, and to other human beings when making judgments about what to do.

For Herbart, educative instruction and moral education reciprocally support one another: Instruction helps the learner expand his or her view of the world with differing and conflicting perspectives, while moral education helps the learner learn to recognize wrong or bad decisions, decide which perspectives will guide his or her actions, and contribute to new ideas of the good.

Perfectibility

Herbart names the perfectibility (*Bildsamkeit*) of a human being as the founding principle of education. The term *perfectibility* is meant to capture the idea that all human beings are capable of being formed by the world and also of forming the world around them. Human perfectibility entails that human beings can be influenced by others and thus educated by others. For Herbart, the fact that human beings can change, engage in self-critique, and alter their directions of thought and action provides the basis for the human capacity to become moral individuals, that is, individuals who make choices that respect others.

Herbart's concept of perfectibility connects to the philosopher Jean-Jacques Rousseau's (1712–1778) idea of perfectibility (*perfectibilité*), which means the ability to learn. The notion Herbart develops also relates to the German idea of *Bildung*, often associated with the work of the philosopher Wilhelm von Humboldt (1767–1835). *Bildung* refers to a process of self-transformation through interactions with the world and others and is most often translated as "education" or "formation."

Herbart's concept of perfectibility has consequences for how we understand the task of the educator. The concept of the human being as changeable neither presupposes that the human being is a blank starting point (*pace* John Locke), nor does it entail that there is a predetermined final endpoint or *telos* to a human being's learning process. By grounding education in the principle of human perfectibility, Herbart makes clear that educators must recognize all human beings as capable of learning, transforming their view of the world, asking questions, and developing an inner censor. Moreover, it brings to the fore the fact that educators must recognize their ability to have an influence on a learner's future. It follows that educators must take responsibility to make conscious choices about how they will influence each learner, without seeking to predetermine the learner's future, a future that can only be decided by the learner. Herbart thus reminds educators that educating is a moral endeavor in which each learner must be given a broad, multifarious view of the world to be able to make decisions for themselves.

Tact and the Teaching Profession

Herbart gives significant thought to the teaching profession and the question of what is entailed in being a good teacher. He developed a concept of pedagogical tact that still has relevance for how we understand the teacher's task today. The concept of tact relates to Aristotle's notion of *phronesis* and can be understood as the teacher's ability to make wise decisions in the moment. According to Herbart, teachers must learn to be pedagogically tactful. This means they have to learn to have distance on educational situations with learners; be innovative and improvisatory on the basis of what the learner brings in terms of questions, understanding, and prior experience; and be able to reflect on and critique their own choices and change.

Herbart's concept of pedagogical tact is important for contemporary discussions of teaching. Tact in teaching, as Herbart develops it, gives a sense of teaching as something much more than a technical task of getting learners to particular outcomes. The concept of tact contributes to understanding teaching as a reflective practice. As such, it involves not only the ability to plan but also the ability to understand and judge what to do in unexpected situations that arise in interactions with learners.

Herbart's thoughts on education give us a vision of education as more than mere socialization. His work influenced American philosophers of education such as John Dewey (1859–1952), who was an active member of the National Herbart Society (which was formed around 1895 in the United States and was renamed the National Society for the Study of Education until it dissolved in 2008). Herbart's theories failed, however, to have a lasting effect in the United States, largely due to the late-19th-century movement called Herbartianism. The Herbartians simplified Herbart's theory of instruction into a rigid method of "steps" that involved teachers getting learners to fixed stages of learning. Although the Herbartians' interpretation of Herbart was limited, this is not to say that Herbart's theory of instruction is beyond reproach. One problem with Herbart's theory of instruction is recognized by Dewey in his *Democracy and Education* (1916). In this work, Dewey points out that Herbart's theory does not adequately take into account the new ideas that the learner brings to learning situations. But this critique only applies to Herbart's theory of cognitive learning, which views learning too strongly as a step-by-step progression toward knowledge that the teacher can regulate; it does not apply to his concept of moral guidance and moral learning.

The reception of Herbart as interpreted by the Herbartians has hindered the fruitful aspects of his work from being acknowledged, such that in the past century, very little has been written on Herbart in the English language. Herbart's concept of moral guidance has strong applicability for renewing our understanding of moral education today. Moral education in his view is not reducible to simple concepts of behavior management, such as seating charts or rules about acceptable behaviors, that we might find guiding teaching practice in today's classrooms. Herbart makes a significant point about moral learning, namely, that it is only through struggle and self-critique of self-interested inclinations that we learn how to make reflective judgments that respect others. Herbart's philosophy of education reminds us of the complexity of educating others, when this is seen as a process of supporting critical thinking.

HERMENEUTICS

Hermeneutics—"a term whose Greek looks, theological past, and Herr Professor pretentiousness ought not put us off because, under the homelier and less fussy name of interpretation, it is what many of us at least have been talking all the time."

—Clifford Geertz, *Local Knowledge* (1983, p. 224)

Hermeneutics is the theory and philosophy of understanding and interpretation. The term derives from Hermes, a son of Zeus, who interprets messages from the Greek gods. Hermes was not simply a messenger, however. He was also a trickster. It was not always easy to determine which role Hermes was playing.

As Hermes's story suggests, understanding and interpretation can be fraught. In education, for example, students sometimes struggle to understand the meaning of texts. Teachers try to understand students' questions and may wonder about the meaning of teaching for their own lives. Educational researchers who use qualitative and quantitative methods make interpretive judgments (albeit for different reasons) and must determine whether their interpretations are defensible. Hermeneutic theory recognizes that interpretive challenges such as these can be analyzed from various perspectives that posit different assumptions about what interpretation entails and what the goals of interpretation should be. Becoming familiar with debates in hermeneutic theory can help us appreciate the interpretive complexities we encounter every day and permit us to become more thoughtful interpreters.

A key debate concerns how interpretation is defined. One definition frames interpretation in terms of epistemology (the philosophy of knowing and knowledge). From this perspective, interpretation is a method or cognitive strategy we employ to clarify or construct meaning. The goal is to produce valid understanding of meaningful "objects," such as texts, artifacts, spoken words, experiences, and intentions.

The second definition frames interpretation in terms of ontology (the philosophy of being and existence). In this view, interpretation is not an act of cognition, a special method, or a theory of knowledge. Interpretation, instead, characterizes how human beings naturally experience the world. Realized through our moods, concerns, self-understanding, and practical engagements with people and things we encounter in our sociohistorical contexts, interpretation is an unavoidable aspect of human existence.

The epistemological and ontological definitions of interpretation interact as sibling rivals. The hermeneutic "family split" arose more than a century ago when beliefs about the practice and aim of interpretation intersected with the success of physical science and the rise of social science. In the course of this entry, we will examine the German branch of the hermeneutic family tree beginning in the 19th century with Wilhelm Dilthey, who argued that interpretation is both (a) a method and a theory of

knowledge for the human sciences and (b) the prereflective mode of everyday lived experience. As will be shown, Dilthey could not reconcile his aspiration for an epistemology of interpretive social science with his realization that interpretation is an ontological feature of human experience that cannot easily be transformed into reflective scientific knowledge.

In the 20th century, Martin Heidegger argued that Dilthey was correct to intuit that "lived" understanding cannot be fully theorized or methodically regulated. Unlike Dilthey, however, Heidegger maintained that scientific knowledge *necessarily* remains indebted to lived understanding. We will explore why Heidegger argued for the primacy of lived understanding. We will also see how Hans-Georg Gadamer drew on Heidegger's hermeneutics to develop an ontological model of social science, which posits that interpretation in social science is no different from interpretation in ordinary life.

Gadamer's ideas have provoked a range of responses. We will look at two contemporary criticisms. One seeks to replace Gadamer's ontological hermeneutics with epistemological hermeneutics. The other appreciates Gadamer's ontological social science but argues that it must be supplemented by method and theory. In conclusion, the entry will briefly review how educational philosophers use hermeneutics to analyze educational practices, aims, and research.

Interpretive Social Science: Dilthey's Dilemma

Wilhelm Dilthey (1833–1911), a Protestant theologian, devoted his life to developing the *Geisteswissenschaften* (German for social science, also translated as the human or moral sciences, or sciences of mind or of the human spirit). Dilthey thought that human beings express their understanding of life experience in the form of meaningful objects, such as texts, works of art, and various cultural expressions, and that interpreting these meaningful objects is fundamental for maintaining social life. Social science therefore requires a hermeneutic method, not the methods of physical science. It also requires an epistemology of interpretive knowledge, not a theory of knowledge concerned with causal explanation. The German word *Verstehen* (interpretation; commonly translated as *understanding*) captures Dilthey's belief that the social sciences are interpretive and, therefore, are distinct from the physical sciences. Dilthey insisted that the two forms of scientific knowledge, while different, are equally rigorous.

Dilthey based his ideas on the *hermeneutic circle*, a method of interpretation that became prominent during the Reformation, when Protestant theologians sought to interpret the Bible without appealing to the Catholic Church to determine the meaning of problematic passages or resolve interpretive disputes. As its name suggests, the hermeneutic method assumes that interpretation is circular. Because the meaning of the Bible was thought to be unified and self-consistent, the meaning of any specific passage could be determined by referring to the text as a whole. But since understanding the text as a whole presumes understanding its problematic passages, determining the meaning of a problematic passage depends on a preliminary intuitive grasp of the text's entire meaning. Biblical exegesis thus revolves in a continuous cycle of anticipation and revision. Interpreting the meaning of any part of the Bible depends on having already grasped the meaning of the Bible as a whole, even as one's understanding of the entire Bible will be reshaped as one clarifies the meaning of its constituent parts.

Another Protestant theologian, Friedrich Schleiermacher (1768–1834), maintained that the hermeneutic circle could ensure understanding not only of the Bible but also of all written and oral expressions. Using this method correctly, interpreters could understand the meaning of linguistic expressions better than the authors who produced them. Schleiermacher transformed the hermeneutic circle from a method of Biblical exegesis into a general theory of interpretation that explained how understanding could be achieved in ordinary circumstances.

Extending Schleiermacher, Dilthey contended that the hermeneutic circle not only helps people reflectively interpret others' meaningful expressions but also enables people to understand themselves and their own lived experience. This is because life experiences do not unfold in linear fashion but, instead, are related to one another as parts are related to wholes. On the one hand, we understand specific life experiences in terms of how we understand the meaning of our life as a whole. At the same time, the way we understand our life as a whole depends on how we understand specific life experiences. Understanding specific experiences thus shapes and also is shaped by understanding the overall meaning of our lives, even as understanding our life's overall meaning both shapes and is shaped by how we understand specific life experiences.

Applying the hermeneutic circle to life, Dilthey realized that understanding is temporal. Past experiences constitute the "parts" of one's biography. The future makes it possible to fathom one's life in toto. Interpreting the meaning of the future depends on and reshapes one's understanding of the past, even as interpreting the meaning of the past anticipates and revises one's understanding of the future.

Interpreting the meaning of time therefore is integral to interpreting the meaning of lived experience. It is important to note that at the prereflective level of interpreting lived experience, time is not an *object* for interpretation. It is impossible to freeze or objectify the past in order to interpret it. Neither is the future a stationary target at which interpretation aims. One rather interprets the meaning of time as one moves through time. Where lived experience is concerned, interpreting time and experiencing time arise together.

Dilthey drew two conclusions from this insight. First, the meaning of life experience is fluid. With the passage of time, the meaning of the past and the future shifts. At different points in the future, one's past will mean different things. The meaning of the future also changes, depending on the particular stage of life from which the future is anticipated.

Second, interpreting lived experience does not produce understanding that is abstracted from the experience of living. We cannot escape our situation to interpret it. Nor can we interpret our life and *then* experience it. Rather, we are practically engaged in living the life that we interpret. Prereflective interpretation, in short, is situated, partial, practical, and personal.

Dilthey believed that prereflective understanding of one's own lived experience could evolve into reflective theoretical knowledge of how other people understand their life experience. Theoretical knowledge thereby extends and refines pretheoretical practical understanding. But Dilthey recognized that because theoretical knowledge is rooted in pretheoretical understanding, knowledge in the social sciences, particularly in history, differs from knowledge in the physical sciences. The historian who reflectively examines the meaning of historical events himself is a historical being. The meaning of the past therefore cannot be established once and for all but instead varies with the perspective of the historian who studies it. Moreover, theoretical understanding remains rooted in the pretheoretical understanding it aims to clarify, even as pretheoretical understanding is changed by the theoretical understanding that it grounds. Interpretation consequently revolves in a never-ending circle, rendering historical knowledge provisional and incomplete.

Although Dilthey believed that the interpretive social sciences could be as rigorous as the physical sciences, the character of knowledge in interpretive social science nonetheless vexed him. What kind of scientific knowledge is possible when the meaning of that which is studied constantly changes? Such knowledge is relativistic, not general and valid. Moreover, insofar as the historian "belongs" to the history he studies, historical knowledge cannot be objective. Historical knowledge instead is subjective, provisional, and partial. The circularity of interpretation raises the possibility that historical "knowledge" simply proves what it presupposes.

In an effort to reconcile understanding lived experience with scientific knowledge, Dilthey turned to his younger contemporary Edmund Husserl (1859–1938). Husserl demonstrated that science grows out of particular "lifeworlds" and necessarily presupposes nonscientific understandings. But while Husserl demonstrated that scientific knowledge depends on prereflectively understanding particular lifeworlds, he also subjected the lifeworld to phenomenological analysis to discover "essences" in lived experience that make theoretical knowledge of the lifeworld possible. In so doing, Husserl encountered a contradiction. On the one hand, pretheoretical understandings are relative to particular lifeworlds. On the other hand, phenomenological analysis aims to produce knowledge of the lifeworld that is universal and unconditionally valid. It was unclear how phenomenological analysis could both transcend and also remain indebted to pretheoretical understanding. Phenomenological analysis seemed both necessary and also impossible. Husserl did not solve Dilthey's dilemma but instead exposed another aspect of it.

Ontological Hermeneutics: Heidegger and Gadamer

Hans-Georg Gadamer (1900–2002) believed that Dilthey was stymied by a false assumption. Dilthey assumed that prereflective understanding is subjective. It therefore is biased and unreliable and cannot be the basis for interpretive social science. Gadamer countered that prereflective understanding is not subjective but instead is intimately and necessarily tied to critical reflection. The intimate necessary relation between prereflective understanding and critical reflection provides an opening for the disclosure of truth.

Gadamer based his ideas on the work of his teacher, Martin Heidegger (1889–1976). In his book *Being and Time* (1962), Heidegger probed two of Dilthey's important insights: (1) we experience the life that we prereflectively interpret and (2) prereflective understanding exhibits a circular temporal structure. Dilthey believed that these two conditions are contingent and apply only to prereflective understanding. Heidegger demonstrated that both conditions are necessary and characterize all understanding, including critical reflection.

Heidegger began by considering the question of existence. To exist, Heidegger reasoned, is to live in the present. As Dilthey showed, the present does not arise in a historical vacuum but instead always implicates the future and the past. Living in the present, we cannot help anticipate the future based on where we have been, even as our expectations for future experience color our understanding of the life we have lived. Heidegger used the term *historicity* to underscore the idea that human understanding is an *inescapably* temporal experience.

Insofar as understanding is an inescapably temporal experience, we do not choose to start (or stop) understanding at a particular point in (or out of) time. Rather, understanding is *a way of being* that always is already going on (to use Heidegger's phrase). It is true that understanding sometimes is mistaken. But breakdowns in understanding signify *mis*understanding, not an *absence* of understanding according to Heidegger.

As an experience that is always happening, understanding does not grasp the meaning of objects that are "present-at-hand," distinct from our interests and concerns. Understanding instead signifies being intimately involved with people and things. Our world is composed of implements that are "ready-to-hand," tied to our purposes, moods, interests, and so on. Heidegger described engaged practical ongoing understanding in terms of "fore-having," "fore-sight," and "fore-conception." The prefix *fore-* signifies that we are able to engage with implements in our world because we prereflectively sense how they are implicated with our interests and how they fit within the context of meaningful relations in which we find them.

The fact that we prereflectively understand meaning does not imply that understanding is stuck in the past. Prereflective understanding can change as human beings move into the future, reconsider prior understanding, and anticipate new possibilities. Heidegger insisted that prereflective understanding could become critical and reflective. But critical reflection does not produce understanding where none had previously existed. Critical reflection instead remains indebted to the preunderstandings it clarifies and corrects.

Heidegger coined the term *thrown-projection* to describe understanding as an experience of being involved in the world. The term *thrown* indicates that we do not construct the meaningful context(s) in which we live. Rather, we are born into a social world that is inherently meaningful and that has already been interpreted by others. Interpretation is possible, because the world discloses meaning through the medium of language. We inherit this social web of meaning as a linguistic "horizon" within which the construal of meaning for our own lives becomes possible. The term *projection* is not synonymous with *planning*, according to Heidegger. Projection instead indicates that understanding is a dynamic experience of anticipating future possibilities. Because expectations for the future necessarily arise in the present, we cannot see them in their entirety or with absolute clarity. Moreover, while future possibilities are open, they nonetheless are partially circumscribed by possibilities that already have been fulfilled.

Heidegger said that the human being who experiences understanding as a cycle of thrown-projection is *Dasein*. *Dasein* means "there-being." Unlike the autonomous epistemological subject who leverages interpretation to grasp the meaning of objects (including objectified experiences), *Dasein* is not an independent agent who confronts discrete objects, the meaning of which he must deliberately choose to discover or construct. *Dasein* rather is "there" in the world, spontaneously involved with things that *Dasein* understands prior to any distinction between subjects and objects. *Dasein* does not initiate understanding and does not regulate the production of meaning. The fact of existing in an inherently meaningful and already interpreted world—not *Dasein's* own initiative—is the condition that makes both prereflective and reflective understanding possible.

Heidegger's claim that understanding is a temporally conditioned way of experiencing the world carries profound implications for social science, Gadamer concluded. He developed these implications in his magnum opus *Truth and Method* (1960/1975). Before sketching Gadamer's ontological view of social science, it is helpful to clarify two points. First, while Gadamer challenged the "science" in social science, he nonetheless used the term

social science (moral science and human science). According to Gadamer, science does not refer exclusively to natural science or exclude the humanities. Like many Continental European thinkers, science for Gadamer refers to systematic study in fields as diverse as theology, archaeology, and politics.

Second, Gadamer did not dismiss natural science. On the contrary, he believed that natural science is necessary and important. But Gadamer wanted to decenter the hegemony of scientific method in social science. He feared that when we rely on method to reflectively understand the social world, we tend to emphasize understanding that we regulate and consciously produce. Consequently, we may delegitimize, occlude, or ignore understanding that we do not control and cannot divorce from our self-understanding and historical situation. Insofar as social science relies on method, Gadamer believed that it alienates us from important dimensions of our ordinary life experience. Overemphasizing method also warps natural science, Gadamer claimed. While method has a place in natural science, magnifying its role conflates natural science with instrumental procedures that negate the importance of interpretive judgment and modesty in scientific practice.

Gadamer thus was not hostile to science. Nevertheless, he sought to significantly reframe *social* science. Following Heidegger, Gadamer argued that interpretation in social science is a temporally conditioned experience or "event" that we live through, not a kind of knowledge that we achieve by methodologically regulating our life experience or by abstracting and justifying critical reflection outside of ordinary understanding. Understanding and interpretation in social science are no different from understanding and interpretation in daily life. In both cases, Gadamer maintained, we experience understanding and interpretation as a dialogue or conversation.

The notion that social science is a conversation might seem startling. We typically think that social scientists collect and analyze data. But the people and texts that concern social scientists are not sources of data according to Gadamer. They are conversation partners.

Texts for Gadamer are conversation partners no less than people. Texts are not inanimate objects in which an author's intended meaning is permanently congealed. Texts are rather dynamic linguistic horizons that disclose meaning over time. Gadamer's social scientist starts to understand a text when she recognizes that it raises a question or issue that does not belong exclusively to the text (or its author) or the question or issue that the text voices comes down through tradition and also concerns the social scientist. Similarly, the social scientist starts to understand another person not because she empathizes with him or is able to leap out of her own body to get inside his head but because understanding begins when the social scientist recognizes the question or issue that concerns the other person and realizes that this question concerns her as well.

Of course, neither party in the conversation can escape the situation into which each has been "thrown." Understanding therefore does not aim to capture *the* meaning of a question. The meaning of a question rather is codetermined by the horizons of the people who interpret it. People who inhabit different horizons will understand the "same" question differently. Insofar as horizons are temporal and change over time, the "same" question will be understood differently every time it is interpreted.

If we necessarily bring our own horizon to understanding an issue, how can we recognize the horizon of our partner? What prevents us from appropriating our partner's perspective or conflating it with our own? Gadamer proposes two answers. First, he notes that horizons are porous, not self-enclosed. In principle, therefore, horizons can interpenetrate.

Gadamer's second answer concerns the disposition of conversation partners. In a successful conversation, each party is open to the possibility that the other's perspective is true and may challenge and even refute one's own understanding. Gadamer insists that one's own understanding cannot be clarified or corrected as long as one entertains the other's perspective from afar and continues to maintain the truth of one's own position. Change instead requires one to *risk* one's assumptions and to actually experience the negation of one's understanding. Gadamer acknowledges that negative experiences are uncomfortable, nevertheless negative experiences can be openings for genuinely reflecting on prior understanding and arriving at new insight into an issue.

Thus, like prereflective understanding, critical reflection for Gadamer is an experience we undergo. In successful conversations, both parties are open to risking their assumptions. As a consequence of being challenged, the understanding of both parties can become more encompassing, perspicacious, critical, and reflective. Gadamer calls the reflective dimension of conversation a "fusion of horizons."

Neither party can predict in advance how its horizons will be fused. When one party tries to direct the conversation or claims to know what the other is thinking, "talk" becomes something other than conversation, Gadamer observes. But when a fusion of horizons genuinely happens, both parties come to understand a truth about life's meaning that neither could know outside of participating in the conversation.

In sum, Gadamer's reframing of social science in terms of a conversation that we experience with others differs from the way we typically characterize social science. Gadamer's researcher does not try to empathize with those whom she studies. Neither does she regard them and their cultures as exotic and distant. Rather, she endeavors to recognize a question or issue that she and her partner share. The meaning of the question cannot be determined "objectively" but instead is codetermined by the horizon of both the researcher and her partner and changes with each interpretive event. The self-understanding of Gadamer's researcher is not controlled or kept out of play but instead is affected by allowing her partner to challenge her understanding of the question that is of mutual concern. The researcher cannot direct this experience or predict the new insight that the conversation will disclose. Instead, she participates in an event that transforms both herself and her partner in ways that neither party can imagine in advance.

Insofar as method helps researchers regulate understanding, Gadamer contends that it distances them from their lived experience. Relying on method seduces people to underplay and even discount the experiential dimension of critical reflection. Social science becomes an intellectual exercise, not an opportunity for personal transformation. In place of honing methodological skill, Gadamer wants social scientists to cultivate the disposition to be open, take risks, and trust that they may have something to learn from their interlocutors. Framing social science as a conversation we experience with others can rehabilitate the moral dimension of social science, Gadamer concludes.

Responses to Gadamer

A number of contemporary scholars are developing the philosophical and practical implications of Gadamer's social science. In his influential essay, "Interpretation and the Sciences of Man" (1971), Charles Taylor (1931–) argues that social scientists are "self-interpreting animals" who always prereflectively understand their theoretical conclusions and who inevitably appeal to intuitions and self-understanding to justify their findings. Ruth Behar (1956–) provides a practical example of ontological social science. Behar's book, *The Vulnerable Observer* (1996), does not explicitly reference hermeneutics or Gadamer. Nonetheless, she argues in it that anthropological insight necessarily implicates the anthropologist's self-understanding; the anthropologist's self-understanding, moreover, is vulnerable to (and affected by) the people whom she studies.

While a number of practitioners and scholars embrace Gadamer, his work also provokes criticism. Thinkers such as Emilio Betti (1890–1968), E. D. Hirsch Jr. (1928–), and Dagfinn Follesdall (1932–) epitomize one line of response. According to these critics, Gadamer's claim that the interpreter's situation influences meaning and that meaning is construed differently in each interpretive event leads to relativism. Moreover, Gadamer provides no basis for adjudicating conflicting interpretations. Adjudication must appeal to an extracontextual criterion, which Gadamer believes is impossible. In short, these critics conclude that hermeneutics should remain under the umbrella of epistemology. They endeavor to show how interpretation is or can become a rigorous method and theory of knowledge for producing valid objective understanding of texts.

Jürgen Habermas (1929–) articulates a second response. Unlike the critics noted above, Habermas appreciates Gadamer's insight into the ontological nature of social science. Presuppositions are always operating, Habermas notes. Understanding is irreducibly contextual, historical, and bound up with the interpreter's self-understanding. The social scientist consequently belongs to the social world that he interprets. Social science theories issue from the pretheoretical practices they strive to explain.

But despite these points of agreement, Habermas questions Gadamer's faith in the power of language and conversation to disclose truth and promote critical reflection. Language is not simply a communicative medium for understanding meaning, Habermas argues. Material conditions and power interests can systematically and insidiously distort meaning in ways that language does not make apparent. Hence, reflection must do more than simply *clarify* lived understanding by means of conversation. Reflection must also help people *distinguish* lived understanding from ideology. Becoming liberated from ideology

requires a theory that can methodically explain the genesis of distortion by appealing to rationally self-evident causes.

Hermeneutics and Education

Contemporary scholars employ hermeneutics to analyze a range of educational issues, including children's rights, teaching and teacher education, science education, medical education, curriculum theory, inquiry-based learning, and validity in educational assessment. Some scholars contrast epistemological and ontological hermeneutics. Others focus on ontological hermeneutics as a framework for critiquing and reframing educational practices and aims. These scholars develop ideas articulated by Heidegger and Gadamer, who sought to interrupt utilitarian, technical, and market-based influences on education that emphasize developing skills and mastering knowledge. Heidegger and Gadamer countered that education is "*Bildung*"—an ongoing experience of self-formation and transformation—in which one learns to become receptive to ways of being that differ from and even challenge one's own horizon. Conceived as *Bildung*, education aims to help students become more reflective and humble as their horizons expand in ways that neither they nor their teachers can foresee.

Hermeneutics also resounds in normative debates about qualitative inquiry. From an epistemological perspective, the central issue for qualitative research is the dilemma that vexed Dilthey: Given that interpretation necessarily presupposes prior understanding that is personal, temporal, and situated within particular sociocultural contexts, how can interpretive conclusions be objective, generalizable, and valid? From an ontological perspective, the aim of qualitative inquiry is not simply to produce knowledge about educational questions. Qualitative research also should aim to *be* educative, catalyzing people to challenge their current understanding of education in order to arrive at new, more encompassing insights and questions concerning education and the human condition.

Debates about specific issues appeal to both Dilthey and Gadamer. For example, Dilthey and Gadamer maintained that interpretation necessarily implicates one's self-understanding and sociohistorical situation. While this idea is axiomatic among qualitative researchers, it nevertheless raises questions about the self-understanding of researchers in relation to the people they study.

Epistemologically oriented qualitative researchers wrestle with how they can control or at least reflectively account for their *own* "positionality" and self-understanding so that they can accurately interpret how their subjects make sense of the world. A key question concerns whether and how self-reflection on the part of researchers can be methodically achieved. Are there methods that can help researchers address challenges to self-reflection that arise in the field? If so, which methods should researchers adopt and under which circumstances?

An ontological view of self-understanding raises different issues. Some collaborative action researchers maintain that research questions should be of mutual interest to both "subjects" and researchers. Reflective insight into these questions cannot arise if researchers keep their understanding out of play. Both parties—subjects and researchers—must allow their understanding to be *critically engaged* by the other so that they might become aware of assumptions they might otherwise fail to notice. From an ontological perspective, the key question is, "How can researchers risk their self-understanding and be open to being challenged by their subjects (and vice versa)?" Learning to risk one's self-understanding is not a methodological achievement. It rather requires researchers to cultivate a certain disposition.

Debates about research as conversation illustrate another set of hermeneutic concerns. Some conclude that while conversation is an ideal to which qualitative researchers should aspire, it is unclear whether and how this ideal can be enacted. Institutional review board regulations assume that the rights of research subjects must be protected. This epistemological assumption makes it difficult, if not impossible, to approach research as a Gadamerian conversation that regards subjects and researchers as equal partners.

Some qualitative researchers adopt a Habermasian view of conversation. They point to a legacy of privilege and marginalization and warn that seemingly openhearted conversations can exploit subjects. Scholars of color who conduct qualitative research in their home communities discuss how their university status distances them from people with whom they were able to easily converse before they became university researchers. For these scholars, the unforeseen insights that arise during research conversations are experiences of alienation, not Gadamerian solidarity.

Finally, hermeneutics figures in debates about the scientific status of educational research. D. C. Phillips

has pursued this issue, arguing for the centrality of interpretation in postpositivist science. While the postpositivist embrace of interpretation came by way of Popper and Kuhn, not Dilthey, Heidegger, or Gadamer, the two views of interpretation are remarkably similar. For example, postpositivists acknowledge that research is mediated by the researcher's historical/cultural situation; observation necessarily is theory laden. With respect to social science, postpositivists recognize that researchers struggle to understand themselves as they endeavor to interpret others. Failing to acknowledge the need for interpretive judgment in science and social science results in a phenomenon that Phillips (2006) calls "methodolatry." Methodolatry conflates research with technical method (specifically, randomized field trials) and discounts research as a uniquely human practice.

Phillips's critique of methodolatry sounds Gadamerian. Unlike Gadamer, however, Phillips takes an epistemological view of social science and distinguishes claims about the empirical world from insights into the meaning of lived experience. The latter implicate self-understanding. The former do not. Openness to being challenged may help social scientists recognize when their conclusions are wrong. But claims about the empirical world can be wrong, *whether or not social scientists acknowledge that they are wrong*. Claims about the empirical world can and must be assessed on their own merit, Phillips stresses, irrespective of their origin or the self-awareness of the researcher who produced them. Assessing the validity of empirical claims and clarifying lived understanding are two different projects, Phillips concludes.

Conclusion

Hermeneutics addresses a range of enduring philosophical questions concerning how human beings understand themselves and the social world. Questions about interpretation are not simply theoretical, however. As hermeneutic analyses of education make plain, questions about interpretation are eminently practical. Questions of practice complicate interpretive theories, generating new questions for theory to clarify and explain.

Hidden Curriculum

A curriculum is a program consisting of a series of learning activities intended to realize some set of educational objectives. The mission of a school or other educational agency is understood to be the delivery of a curriculum to some group of students or other learners. Generally, the content of a curriculum is announced so that students and other stakeholders are aware of what learning opportunities are available at a given school or set of schools. It is the case, however, that not all of a school's learning opportunities are advertised—schools also feature a hidden curriculum whose objectives and learning activities are seldom spelled out. This hidden curriculum is implemented via routines and attitudes instilled through students' experiences with the explicit curriculum and its milieu; these experiences may be consonant or dissonant with the explicit curriculum. In any case, the instructional outcomes generated by these routines and attitudes are often judged by scholars and social critics to be more significant than those generated by the explicit curriculum. Therefore, ignoring the hidden curriculum is a stumbling block to disclosing the true character and outcomes of any curriculum. This entry discusses how the term *hidden curriculum* is used to refer to a variety of aspects of schooling, including collateral learning, socialization, and perpetuation of advantages based on gender or class.

In the education literature, the term *hidden curriculum* has been used in a number of different ways that are not always consistent. While all senses of the expression imply that it is somehow obscured from general notice, commentators otherwise define it variously and explain the intentions of its creators differently. Hidden curricula are often singled out to identify some educational ill, although it sometimes is argued that they can also take benign or positive forms.

John Dewey wrote about one meaning of hidden curriculum in *Experience and Education* (1938). He drew attention to how "collateral learning" (e.g., of habits and attitudes) affects what students take away from their encounters with subject matter. This collateral learning, he argued, holds equal or greater educational significance than the explicit curriculum because the habits and attitudes instilled have more lasting effects on students than the subject matter itself. There is now persuasive empirical evidence in support of Dewey's view, such as *The Subject Matters: Classroom Activity in Math and Social Studies* (1988) by Susan S. Stodolsky.

Philip W. Jackson is often credited with coining the term *hidden curriculum*. In his influential book *Life in Classrooms* (1968), Jackson portrays hidden curriculum in a manner related to, yet discernible from, collateral learning as described by Dewey. Rather than being focused on the subject matters of the curriculum, such as spelling and history, Jackson is more concerned with how classroom life socializes students to certain norms, expectations, and routines, such as working in a solitary fashion among a crowd of other students. In a similar vein, he points out how schools reward certain behaviors, such as compliance and patience. Jackson affords more significance to these types of factors than to the particular subject matter under study. One way of summing up Jackson's thesis is that patterns of repeated behavior over thousands of hours of classroom life, although seldom remarked on as the salient feature of schooling, may have a bigger cumulative effect on students than the formally announced curriculum. In a later book, *Untaught Lessons* (1992), Jackson further explored the implicit long-term effects teachers have on students.

The attitude Jackson adopts toward the hidden curriculum in *Life in Classrooms* could be considered neutral. Nonetheless, his book and other works with related themes, such as Robert Dreeben's *On What Is Learned in Schools* (1968), appeared during an era of widespread criticism of dominant societal values. Part of this criticism was directed at schools, particularly their role in perpetuating educational inequities. This context seems to have contributed to the keen interest educators took in hidden curriculum at the time. Whereas traditionally answers to what students take away from school referenced the objectives and content of the explicit curriculum, this type of response became regarded as discordant with reality when outcome measures showed that some groups benefited far more from school programs than other groups. In particular, attention was now drawn to how the hidden curriculum discriminated among students on grounds of gender, race, social class, and, in time, sexual orientation.

For example, investigation of gender and the hidden curriculum showed various ways in which girls were disadvantaged relative to boys. For instance, instructional materials were found to feature sexist assumptions while teachers gave more attention to boys than girls. Some of these practices were so overt that there was room for doubt as to whether it was warranted to designate them as cases of *hidden* curriculum.

Yet another sense of hidden curriculum centers on underlying forces that lead to schools reproducing the existing social and economic order. While related to the concern about discriminatory practices just mentioned, this perspective has been inspired by critical theory. It conceives the hidden curriculum as a mechanism by which schools legitimate the success of some students and the failure of others. Thus, schools serve to discriminate along the lines of social class, effectively assigning successful students to a path leading to managerial and professional positions and the rest of the students to skilled and unskilled labor positions. This view of the hidden curriculum came into prominence in the 1970s. In England, Paul Willis explored the role of schools in assigning working-class children to working-class jobs; Michael W. Apple and Linda McNeil were important voices for this line of thought in the United States. McNeil in her *Contradictions of Control: Social Structure and School Knowledge* (1986) argued that the underlying organization of high schools ran counter to realizing announced objectives such as teaching critical thinking. Rather, the unannounced objectives were set by forces beyond the classroom and were aimed at efficiency and control, which undermined the possibilities for engaging teaching and substantive learning. Skeptics of this critical line of thought asked, however, "*Who* or *what* was furtively organizing schools to these ends?"

Sometimes, "hidden curriculum" has been used to mean what schools do not make available—that is, what is not taught. This usage draws attention to the consequences of curricular neglect, since what is not taught is more than a neutral void; it limits what one can think about and the possibilities one can consider. According to Elliot W. Eisner, this is more properly termed the *null curriculum* since it connotes absence rather than lack of visibility.

The hidden curriculum has also been studied as a hindrance to educational change. For instance, the fate of instructional reforms or curriculum changes rests as much on school culture—much of which is in the hidden curriculum—as it does on announced and visible changes. This, according to Seymour Sarason, is a problem as the hidden curriculum serves as an obstacle to change. From this perspective, change generally stays at the surface level, leaving the basic workings of schools largely in place.

Higher Education: Contemporary Controversies

Higher education comprises formal or institutionalized education, leading to the awarding of recognized qualifications beyond the level of secondary schooling. It is defined in a variety of ways in different nations; in some countries, including parts of Europe and Australia, "higher education" is confined to degree-granting programs normally of three full-time years or more in duration. However, in some other countries, such as the United States and Canada, subdegree programs of two full-time years are included, while in some jurisdictions, shorter programs are included. The Organisation for Economic Co-operation and Development, which

publishes an annual series of comparative statistics on education, remakes the problem by focusing on "tertiary education" and dividing that category into degree and selected subdegree programs.

A related issue is the definition of *university*. This is variously regulated by legislation and custom, and again with a range of approaches. Some jurisdictions confine the title to institutions that conduct formal research activity. Others admit teaching-only institutions. Not all university programs entail degrees, and the length of programs varies greatly. In practice, however, the designation *university* tends to be more exclusive than *higher education*, which in many countries includes institutions designated as *colleges*, *institutes*, or with other titles, as well as *universities*. This entry discusses the role of higher education, the effects of growing enrollment in higher education, and tensions between the state and institutions of higher education.

Competing Narratives of the Role of Higher Education

Higher education institutions together are among the most connected of social sectors, and they are also relatively highly internationalized. Higher education is less ubiquitous than government or financial institutions but equivalent in the scale and scope of its networked relationships with churches and major professions. It includes a large proportion of national populations in its activities, at one or more stages of the life cycle, and is closely connected to government and to all organizations in knowledge-intensive economic and occupational activity.

Higher education is also attended by continuing controversies, for two reasons. The first reason is that higher education is the subject of different narratives concerning the social functions of the sector. These narratives, partly sustained by the various connections between higher education and other sectors, shape its practices. The purposes of higher education are many. The concept of the "multiversity," outlined in the 1960s by the then president of the University of California, Clark Kerr, was intended to capture this. The different narratives combine in often eclectic ways, and under some circumstances, they are in tension. There are various, often ill defined, and competing claims about higher education concerning its roles in individual and social formation, the allocation of social opportunities and fairness in that allocation, political democracy and the formation of citizens, international relations and global cosmopolitanism, economic productivity and the creation of employment opportunities for graduates, and even its contributions to culture, the arts, and civilization. It is impossible for any set of institutions to meet all such expectations simultaneously, expectations that are themselves subject to many interpretations.

The second reason why higher education is open to controversy is that it is primarily shaped by nation-states and open to the techniques of governmental control but needs some institutional autonomy and academic freedom to carry out its functions, especially in research. Government–institution tensions are endemic, especially in those countries with a liberal tradition, such as the English-speaking democracies.

These matters play out in different ways in national higher education systems. In addition to North American higher education, the most influential form, and higher education in the other English-speaking countries, there are distinct approaches to higher education in France, Germany, the Nordic zone, Russia and other European countries, China and the rest of East Asia, South Asia, Southeast Asia, Latin America, and elsewhere. All research universities have much in common, especially in the sciences, and have moved closer to each other in the era of the Internet through cross-border networking and mobility of people, global academic publishing, and the normalizing role of global university rankings that began in 2003. But national differences remain, especially in political cultures and state–institution relations, in the structuring of the academic profession, and in the financing of higher education. In some countries, the sector is largely funded by governments; in others, the funding is shared by students or households. While there are common trends and issues as discussed here, these are articulated through national systems in distinctive ways.

The classic 19th-century notions of the university, associated variously with John Henry Newman and with Wilhelm von Humboldt's idea of *Bildung* (German for *education* and *formation*), focused on the formation of personal attributes. Whereas Newman emphasized engagement in intellectual disciplines as an end in itself, and refused the possibility of other ends or purposes of education, the German tradition emphasized self-cultivation through learning, coinciding in this respect with Confucian tradition, and it was more open as to the uses or applications of higher education. These

traditions remain influential. More recent narratives have focused explicitly on the uses of higher education and its relations with other sectors and purposes. In a rebuttal of Newman, Clark Kerr titled his authoritative summary of the workings of the post–World War II higher education as *The Uses of the University* (1963).

As noted, the growth and development of modern mass systems of higher education have been shaped and largely financed (albeit to varying degrees) by nation-states. States emphasize the contributions of higher education to national economic development and its role in the provision of social opportunity. Increasingly, state policy also focuses on the role of higher education in augmenting the global capacity and competitiveness of the national economy and the contribution of research and research training to economic innovation. At the same time, the growth of popular demand for higher education, especially among middle-class families, continually drives governments to expand provisions of higher education. This is true in both multiparty electoral democracies and in one-party states such as China, Singapore, and Malaysia. Governments gain support by expanding educational opportunity. The nexus between popular demand for, and state-regulated supply of, higher education is associated with narratives about access, participation, and equality of opportunity. In addition, in many national systems, the focuses on economic development and educational opportunity are joined to discussions about the employability of graduates. There is recurring unresolved debate about whether higher education is responsible for graduate unemployment and what, if anything, it can do to enhance employability.

Since the early 1960s, the dominant policy narrative of vocational and higher education has been human capital theory. Summarized in the work of the Nobel laureate Gary Becker, human capital theory models education as an investment in the augmentation of individual economic attributes. It argues that the economic effects of education can be measured by calculating the difference between the lifetime earnings of graduates and those of nongraduates, though some human capital economists discount the calculation of rates of return for factors such as individual ability. In essence, human capital theory imagines that an increase in individual capability will increase the individual's intrinsic productivity; this triggers an increase in earnings, regardless of the state of the macroeconomy, fluctuations in labor market demand, the stratification of work opportunities, and the role of educational institutions in social selection. The enhanced earnings of graduates in turn feed into macroeconomic growth and prosperity. This narrative ascribes a central role to higher education in driving economic growth and suggests that the better the quality of higher education, the more effective will be its economic contribution. While conclusive empirical grounding for human capital theory is lacking, it remains influential.

Some economists and sociologists pursue an alternative narrative—screening theory. This models education not as a contributor to intrinsic productivity but as a signaling and queue-ordering device that facilitates employee selection of personnel. Human capital theory emphasizes the supply side of the education–economy relationship, and it assumes that education gains value from its intrinsic usefulness; screening theory emphasizes the demand side, and it assumes that education gains value from exchange in the labor markets. Human capital theory implies that more public and/or private resources should be invested in higher education to lift economic growth, whereas screening theory does not. Human capital theory suggests that any student placed in a higher education discipline ought to generate equal returns on investment; screening theory is more consistent with stratification in the value of institutional brands. On the whole, human capital thinking has been dominant in shaping policy, sustaining the expectation that more and better higher education should advance economic growth. However, government commitment to the value of investment is variable. Conditions of economic boom mostly favor an expansion of both state and household investment in higher education. Conditions of economic recession can trigger either increases or decreases in state investment and tend to depress levels of household spending.

Massification of Higher Education

Nation-building policies, economic agendas, and social aspirations, often but not always joined to demographic growth, combine to drive the continuous expansion of higher education systems almost everywhere. In an influential paper published for the Organisation for Economic Co-operation and Development in 1974, Martin Trow theorized the evolution of national higher education systems from an "elite" phase in which the rate of participation of young people was no more than 15% of the

age-group, to a "mass" phase in which the participation rate was between 15% and 50%, to "universal" systems with participation more than 50%. He argued that each phase was associated with distinctive institution and systems designs, curricula, and social expectations. Discussion of higher education and social opportunity is often joined to democratic narratives favoring the expansion of opportunity to include all citizens and the enhancement of relative opportunities for social groups underrepresented in the higher education sector. These social groups include women, ethnic minorities, people from rural and remote districts, and people from home backgrounds where income or parents' education is lower than the mean. In the past 30 years, in almost every national system, the overall participation of women in higher education has improved dramatically, so that women often outnumber men, except in a few disciplines such as engineering. In contrast, it has proven difficult to lift the relative proportion of students from poor backgrounds despite significant policy effort in many countries.

Yet the drive for expansion also embodies powerful desires for individual social status and relative advantage, if necessary at the expense of others; and equality of opportunity policies have often focused primarily on ordering a fair competition for scarce high-value places. The different institutions and disciplines do not necessarily confer equivalent value. For example, medical degrees confer relatively high value in terms of both social status and lifetime earnings. The paradox of status competition in education is that the more that aspiration and opportunity become universal, the harder it is for the average place in higher education to provide exalted status, as the number of positions that can provide relative advantage is fixed. Positional competition is a zero-sum game, as Fred Hirsch pointed out in *Social Limits to Growth* (1976). In most, though not all, countries, higher education institutions are ranked in hierarchical terms, whether formally in a system of institutional classifications or informally through social convention and reputation. Trow's elite system of higher education, centered on the strongest universities, seems to survive inside the mass or universal systems.

National research universities, supported by the government, play a leading role in nearly every national system. Only in the United States are most of the leading institutions located in the private sector. In other respects, there are marked variations in system organization. The degree of diversity of institutions itself varies significantly. Some systems exhibit a stable division of labor between institutional types, while in others, there are endemic boundary disputes, contestation over primacy in specific niches, and upward "academic drift" away from established missions. The role of institutions in research and the degree of selectivity of students at the point of entry are differentiating factors. In some systems, like the British, the norm is the large-scale comprehensive teaching and research institution active in most disciplines. In other systems, there are many specialist teaching institutions, which can be of high or low status. Some systems, following a pattern established in France and subsequently in Russia, provide specialist elite teaching institutions and maintain strong nonuniversity research institutes, though there is a trend toward large-scale comprehensive teaching/research universities, which is encouraged by the norms underpinning global university rankings. China has moved from the Soviet model toward the American science university model. In parts of Latin America, the leading universities are organized on a very large scale, exceeding 200,000 students, and located in many sites, providing both leadership training and social access and conducting a large proportion of national research. The role of the private sector varies from country to country. In some countries, all or nearly all institutions are public. In some systems, the private sector is largely confined to low-value, for-profit producers, triggering concerns about quality. In others, nonprofit institutions play a variety of roles. Private-sector quality, especially in the for-profit subsector, is often a concern.

In all countries—whether higher education is conceived as a market or as part of civil society, as in the United States, or is understood to be a branch or aspect of state—the most common location, the system boundaries, the stratification, and the division of labor between institutional types are ordered by governments or public authorities. Even private institutions are closely regulated, except in cross-border online education.

State–Institution Tensions

The continuous state–institution tensions play out in differing ways by country. A wide range of arrangements are in place, from systems where higher education is a branch of the state, university leaders are appointed by ministers, and faculty are paid as public servants to systems in which universities

are governed by independent boards or councils that appoint the executive leadership and fix rates of pay. In some countries, institutions select their own students; in others, the allocation of places is determined by government. Everywhere, however, institutions of higher education, in particular research universities, need partial autonomy. They must exercise their own scholarly judgment to be effective in knowledge production—in most countries academic freedom is seen as a normal operating condition for teaching and research, though the definition of academic freedom varies and manifestations of freedom can be contested. American tradition links academic freedom to tenured (permanent) employment and conceives of that freedom largely in terms of freedom from constraint or coercion by the state, but these are not norms in all systems—and in the United States, faculty can be constrained by university managers or by market forces. For example, companies supporting biomedical research via grants and contracts may seek to restrict research activity and the free flow of research findings. In East Asia, notions of academic freedom are closely joined to responsibility and conceived more in terms of positive freedom—that is, the freedom to act or enable—rather than negative freedom. Some conventions treat academic freedom as confined to the knowledge specialization of the scholar or researcher; others treat it as a general right to make public comments in any area. At the same time, states emphasize the utilities of institutions and seek to manage their autonomy within defined policy parameters and externally determined ends. In some countries, institutional autonomy and academic freedom are more restricted, especially in those countries in which university leaders are appointed by government.

Many governments now favor business and quasi-market models in institutional organization and system design, such as competition in the allocation of research funding and other resources, product formats, strategic executive leadership, financial autonomy for institutions, and expectations that institutions raise some of their own funding. In some systems, tuition fees have markedly increased in the context of a consumer model of institution–student relations. These measures have been accompanied by a weakening of professorial self-government, growth in the power of the university executive, and the growing role of the institution *qua* institution and of its brand, though the academic disciplines also continue to shape practices, especially in the leading universities. The widely used triangle model of higher education developed by the sociologist Burton Clark, incorporating interaction between state, academic oligarchy, and market, requires modification to include the university executive as an influential factor. In some countries, the partial shift from state funding to private funding is associated with a weakening of government commitment to the public role of institutions. While most systems retain a policy commitment to securing broad social opportunity in higher education, this commitment rarely extends to providing equal access of all social groups to the leading institutions—social outcomes based on meritocratic competition still prevail. Though this is consistent with the market model, unequal social outcomes generate continued controversies.

High-Stakes Testing

High-stakes testing is a significant aspect of educational assessment in much of the developed world. The phrase indicates that test results are being used to judge the quality of schools and teachers. Such judgments may have serious consequences for the individuals and institutions concerned.

Many feel that such a function for assessment is just one manifestation of an "audit culture" increasingly prevalent in contemporary society, where a variety of agencies and individuals are mistrusted and are believed to require intensive scrutiny to prevent them from "failing." The accountancy metaphor captures many fields, including health care, university research, and social services; they are "audited" by focusing on certain kinds of performance data. Critics argue that high-stakes testing corrupts learning and distorts the curriculum. In contrast, its supporters assert that it raises educational performance. This entry discusses the arguments for and against high-stakes testing, the reasons it is difficult to compare test results across time periods, whether "teaching to the test" skews results, and how the reliability and validity of tests are judged.

Defenders of high-stakes testing note the high cost of education, the importance of safeguarding children from incompetent schools and teaching, and the growing significance of education for competitive industrial economies in globalized markets. They argue that schools themselves should be only too willing to cooperate with our contemporary audit culture if they are genuinely committed to the highest possible educational standards. Champions of current testing functions claim that they play a crucial role in "driving up" educational standards; schools know that poor results will be exposed in published "league tables"—tables ranking schools by performance—and that the mass media will relish the opportunity to expose "inadequate" performers. Moreover, there is said to be strong public support for accountability focusing on tests and widespread appreciation of the easy availability of information about educational institutions in the form of exam grades. Some feel that teachers' very aversion to high-stakes testing suggests that they are afraid of rigorous scrutiny.

Claims about driving up standards are in need of careful scrutiny and analysis. There will be assumptions about what counts as changes over time, about how to detect them, and about what account of "educational standards" is defensible in the first place. Tests can either be *norm referenced*, where a pupil's ultimate grade reflects how well the pupil did compared with others who took the same test, or *criterion referenced*, where test responses are judged according to criteria purporting to describe relevant knowledge, understanding, and performance. Examples of the latter include "count up to 10 objects," "read and write numbers to 10," "decode familiar and some unfamiliar words using blending as the prime approach," and "show some awareness of punctuation marks, for example, pausing at full stops."

Only criterion-referenced tests could, even in principle, have the potential to detect real changes in educational achievements over time. On the face of it, we could discover, for instance, that more seven-year-olds can read and write numbers up to 10 than was the case a decade ago. Norm-referenced tests cannot do this: Grades reflecting how well a student did in comparison with fellow students on a particular occasion can tell us nothing about standards over time.

In some countries where high-stakes testing is combined with a criterion-referenced approach, examination scores have steadily improved. The United Kingdom furnishes us with some examples of this, in the form of National Curriculum tests taken by 11-year-olds and General Certificate of Secondary Education examinations taken by 16-year-olds. There is much controversy over how to interpret such trends. The phrase *grade inflation* is often used in this connection, and it implies that the "same" levels of knowledge and understanding are being awarded higher grades as the years go by. This interpretation is popular with many lay people in the developed world, who have the impression that each generation of school leavers does *not* know and understand more English, mathematics, and so forth than earlier generations.

However, a host of challenges confront any attempt to justify the accusation of grade inflation. Admittedly, in a high-stakes assessment culture, it is likely that teachers have grown more and more skilful at eliciting good test performances whether or not the pupils actually know and understand more. Yet the alleged divide in this supposition, between "real" knowledge and understanding, on the one hand, and test performance, on the other, can only be supported where the tests purport to measure underlying understanding, rather than factual recall or proficiency in observable procedures and skills.

One illustration of the latter might be questions about multiplication, offered rapidly by the tester with the requirement that pupils write their answer immediately. The former might be exemplified by questions involving word problems such as "Mum drives 143 kilometers altogether to visit her aunt. She stops after 47 miles for a coffee. How much further must she drive to reach her aunt?" Here, students must determine which combinations of arithmetical operations are required to arrive at the answer. Such problem solving seems to require an underlying understanding of the relevant arithmetical operations. Note also that at a deeper philosophical level, this whole narrative deserves a proper account of "underlying understanding" that explains how it differs from and yet is manifested by observable performances.

Some empirical researchers have investigated standards over time by repeating exactly the same test on randomly selected groups from each year's pupils. They compare these results with data from different kinds of tests where any one version is not absolutely identical with, but is devised to be "equivalent" to, previous tests. Suppose repeating exactly the same test provides scores that are steady over several years, while grades derived from the merely "equivalent" tests rise in the same period. This at least raises the possibility that the latter tests are afflicted by "grade inflation."

Since test results have been made to matter so much, many educators have felt compelled to *teach to the test*. Broadly speaking, this phrase captures teaching that maximizes pupils' chances of scoring highly in tests without regard to what they actually learn during this process. *Teaching to the test* also indicates teaching focused on the subjects and content to be examined, rather than on other unexamined subjects. So, for instance, in the English tests for 11-year-olds in England, "speaking and listening" have never been assessed. Hence, less attention is given to speaking and listening than to reading and writing.

It may be objected that criticisms of teaching to the test have been overblown and have failed to distinguish between significantly different kinds of learning and teaching. For instance, where specific skills and factual recall are concerned, teaching to the test would seem to be the obvious strategy. If a pupil needs to know irregular French verbs or how to play the scale of A minor on the piano, the kind of teaching that improves the chances of demonstrating just these facts or skills in the relevant test would seem to be wholly justifiable. On the other hand, where the material to be learned very obviously cannot be comprehensively characterized in terms of skills and factual recall, teaching that exclusively focuses on *performance* does seem open to serious objection. Examples crucially involving some depth of understanding include the idea of a "fair test" in science, grasping the concept of a function in algebra, and appreciating the significance and influence of the contexts in which literary texts are written and received in English literature.

Nevertheless, some educators claim that teaching for understanding can, at one and the same time, be the most effective way to boost test performance in any case. The obvious difficulty here is that teachers under pressure from high-stakes testing find this claim hard to accept. Critics of high-stakes testing urge that verdicts on high-stakes assessment must be informed by realism about how teachers feel about the pressures they suffer.

Traditionally, tests are rated in terms of their reliability and validity. Reliability relates to the test's *consistency*. There are several ways of construing this feature, including whether, for instance, different graders would score a particular test paper in the same way or whether someone taking the "same" test on different occasions would obtain the same score each time. Validity concerns whether the test actually measures what it is supposed to measure. So a math test involving problems expressed in words, when administered to a group of pupils whose first language is not English, might not be a *valid* measure of their mathematics achievements, but instead, it may be a misleading indicator of their capacity to read and understand English.

One way of expressing the criticism of the kind of teaching to the test encouraged by a high-stakes regime is that it tends to corrupt the validity of the tests concerned. This criticism makes most sense where the tests purport to measure "real understanding," rather than mere observable performances, since much teaching to the test is held to concentrate on the latter. Of course, if the test is *intended* to measure skills directly, then the worry about corruption of its validity makes little or no sense.

Assessment experts have long debated a tension between test validity and test reliability. Evidently, where tests are performing a high-stakes accountability function, strong levels of reliability are crucial. Perfect reliability is, of course impossible, but schools and teachers expect high levels of consistency when their futures depend on it.

It may be argued that certain types of learning achievement resist consistent assessment. Yet it is not at all obvious that *all* such achievements are educationally unimportant. Candidates for learning of this kind involve pupils in making interpretations and value judgments. Consider, for instance, criteria drawn from English literature exams that include phrases such as *communicate content and meaning through expressive and accurate writing*, and *engage sensitively and with different readings and interpretations demonstrating clear understanding*.

Securing intergrader consistency in the face of such phrases requires examiners to reach uniform verdicts about pupil responses. How can such consistency be achieved? One expedient is for a grading scheme to specify readily observable or measurable proxies for the rich content concerned. For instance, *sophisticated use of sentence structures* might be translated into directly observable text features such as *varying length of sentences*, *using the active and the passive voice*, *beginning sentences with a variety of phrases*, and so on. Now, defenders of the possibility of consistency might dismiss this way of achieving it as manifestly absurd, deliberately designed to undermine their position. They may claim that professional graders can manage perfectly well without proxies, being quite capable of working together to achieve a suitable consensus in verdicts.

Yet such a consensus implies that graders are making very similar interpretations of the responses, backed by a remarkable coincidence in relevant value judgments. Arguably, this is at least suspicious, and if it results from some kind of imposition from an examination authority, it raises the question as to whose value judgment or interpretation would be regarded as definitive, and why. On the face of it, pupil responses of the kind under discussion *should* elicit a variety of reactions from examiners. If such variation is undermined, some would argue that the interpretations themselves are being corrupted.

Homeschooling

The modern phenomenon of homeschooling, or "home education," takes a variety of forms, but typically, it involves parents assuming primary responsibility for the schooling of their child—either by providing direct instruction themselves or by arranging learning opportunities such as online coursework, community-based programs, or selected classes from institutional schools. Although the United States has the largest number of homeschoolers by far (perhaps 4% of the school-aged population), the practice appears to be growing in many countries. Philosophical analysis is typically brought to bear on homeschooling in two ways: (1) theories of learning and (2) the relative interests of parents, children, and the state.

Perhaps the ultimate in individualized and privatized education, homeschooling challenges modern notions of institutionalized schooling and standardized curricula. Homeschoolers' varied practices reveal a wide range of philosophies of curriculum and learning. On one end of the spectrum is "unschooling," which relies on the child to direct the shape and direction of learning. Similar in some respects to institutional "free schools," where no formal curriculum is imposed and students decide what questions or topics to explore, unschooling is based on the conviction that children's natural

curiosity provides sufficient motivation and direction necessary for successful learning. By contrast, other homeschoolers choose to replicate the curricular and motivational structure of much institutional schooling, with fixed schedules and assignments. In contrast to unschooling, this structured approach to homeschooling views external requirements as necessary for learning. Not surprisingly, religious conservatives—whose typical views of "original sin" include children's motivations and behavior—tend toward the more structured end of the homeschooling curricular spectrum.

While philosophies of curriculum and learning obviously play an important role in the shape of homeschooling, the bulk of philosophical literature on home education focuses on its implications for the varying—and sometimes conflicting—interests of children, parents, and the state. Parents have an obvious interest in the education of their children; beyond wanting their children to gain academic proficiency, parents seek to instill certain values and commitments. Children themselves have interests at stake; besides intellectual skills, children need to develop a sufficient degree of personal autonomy—having an array of life choices, as well as the capacity to think and decide for themselves about those choices and the people they want to become. Finally, the state has an interest in the development of citizens who can contribute to society, both in terms of economic self-sufficiency and civic participation.

Philosophical arguments typically focus on the tensions sometimes inherent between these respective interests of parents, children, and the state. Parents may have educational goals and priorities for their children that conflict with their children's own best interests. For example, parents may envision a certain career for their son against his wishes or seek to foreclose certain life options for their daughter (believing that females should not be encouraged to have a professional career). Tensions can arise between the interests of the parents and state as well. In liberal democratic societies marked by value pluralism, the state depends not only on the development of economically self-sufficient citizens but also on individuals who can engage respectfully with fellow citizens representing a diverse array of values and ways of life. This educational goal may be in tension with familial, religious, or cultural beliefs that oppose such engagement. In extreme cases, for example, a homeschool parent might sequester the child from interactions with all but the most like-minded people.

Complicating the analysis of relative interests are often conflicting philosophical visions of the requirements of personal autonomy, in terms of what is necessary for both personal fulfillment and virtuous citizenship. In colloquial terms, autonomy can be said to involve thinking and acting for oneself, but liberal theorists differ widely on what exactly this means, not to mention what it would look like or how to determine whether it has been achieved. Some emphasize the ability to shape one's life course from an array of choices, which raises questions about what it means to freely choose. Other accounts emphasize careful reflection on one's beliefs and values, ultimately revising or affirming those core convictions.

Homeschooling is often the site of profound disagreements over the proper role of the state in ensuring that all children realize their interest in developing essential academic skills. Although there is little dispute, either philosophically or legally, that parents have the right and responsibility to raise their children, this consensus does not extend to parents' control over formal schooling. Many homeschool advocates contend that the educational realm should be understood as simply part of the broader framework of parental rights and responsibilities. But parental rights, like any set of rights, are not unlimited. In matters of children's basic welfare and the role of social service agencies, for example, parents have the right to raise their children as they see fit, and the state may not intervene unless compelling evidence exists that children are being abused or neglected. The burden of proof, so to speak, is on the state—parents are not required to submit yearly "child welfare progress reports." In the same way, homeschoolers often assert that parents' rights to direct their child's education should be infringed on only if there is evidence to suspect that they are neglecting this responsibility. Many theorists and legal analysts, however, draw an important distinction between schooling and parenting and insist that the burden of proof regarding homeschooling's effectiveness rests with parents—thus justifying more extensive state oversight.

Not only does homeschooling pose important philosophical questions as a particular educational practice itself, it also points to the increasingly complicated calculus of the state's role in children's schooling more generally. The rise of cyberschooling and distance education has begun to blur the boundaries between formal schooling and informal education in ways that make the oversight role of the state

less clear and more difficult to navigate. What counts as formal education—and what authority the state should have over it—is a question whose relevance will only increase as educational choices proliferate.

House of Intellect, The

Jacques Barzun (1907–2012), a noted American educator, used *the house of intellect* as the title of an influential book, first published in 1959. The house of intellect encompassed "the persons who consciously and methodically employ the mind; the forms and habits governing the activities in which the mind is so employed; and the conditions under which these people and activities exist" (Barzun, 1959, pp. 3–4). Many writers have since come to use the phrase as a loose synonym for the institutions of higher education. Barzun actually wrote about it with a more complicated, distinctive meaning.

Barzun's *The House of Intellect* exemplified his gift for engaging, lucid prose; his concern for the condition of education at all levels; and his questioning convention and fashion, all to strengthen important forms of thought and action. Barzun wrote about a collective capacity, intellect, which he thought was important yet poorly maintained. At the time, Barzun was provost of Columbia University, a cultural historian of great stature who could address a wide range of topics—from baseball and crime stories to Berlioz and all aspects of Western culture—to an extensive, nonspecialized audience. The phrase—*the house of intellect*—stuck, perhaps better than his diagnosis of its plight.

Barzun distinguished *intellect* from intelligence—intelligence was a universal trait of persons, but specific persons constructed *intellect*, a social force supported by special forms and institutions. Intellect was "intelligence stored up and made into habits of discipline, signs and symbols of meaning, chains of reasoning and spurs to emotion—a shorthand and a wireless by which the mind can skip connectives, recognize ability, and communicate truth" (Barzun, 1959, p. 5). The alphabet and its many uses typified the achievement and resources of intellect. The house of intellect had structure and furnishings, as well as component parts and routines, all of which needed care and maintenance.

Intellect had problems of its own making: its abdication of its virtues and capacities. Intellect was losing three strengths—(1) its status as a distinct group apart from others; (2) its abiding effort within to keep its working tools, particularly skills of literacy, in good order; and (3) its confidence that

> with a cautious confidence and sufficient intellectual training, it is possible to master the literature of a subject and gain a proper understanding of it: specifically, an understanding of the accepted truths, the disputed problems, the rival schools, and the methods now in favor. (Barzun, 1959, p. 12)

Readers often interpret Barzun as a conservative elitist, but doing so blurs what is unique in his thought. He generally spoke for matters such as intellect, which had direct and indirect value to all, and he criticized popular and elite developments that diminished them. With intellect, Barzun warned that art, science, and philanthropy were powerful forces abetting the internal weakening of intellect. Art liberated the spirit by celebrating ambiguities but harmed intellect, which could not maintain its standards of precision as devotion to art became too single minded. Science shared with intellect a commitment to precision, but it created difficulties because its jargons and narrow foci made the commitment to common knowledge more difficult. Finally, philanthropy, a pursuit of "free and equal opportunity as applied to things of the mind," weakened intellect's drive to precise discrimination and judgment.

Barzun's book addressed "the state of the language, the system of schooling, the means and objects of communication, the supplies of money for thought and learning, and the code of feeling and conduct that goes with them" (p. 6). These topics summarize well the concerns animating all of Barzun's writing over his long and productive career. For instance, through cultural history, his main professional calling, Barzun was exploring in one way or another "the code of feeling and conduct that goes with" thought and learning:

Superstition: *Race: A Study in Modern Superstition* (1937) and *Darwin, Marx, Wagner: Critique of a Heritage* (1941)

Romanticism: *Romanticism and the Modern Ego* (1943, expanded in 1961 into *Classic, Romantic, and Modern*) and *Berlioz and the Romantic Century* (2 volumes, 1950 and subsequent editions)

Music: *Berlioz, an Anthology on the Pleasures of Music* (1951) and *Music in American Life* (1956)

Art and literature: *The Energies of Art: Studies of Authors, Classic and Modern* (1956), *The Use and Abuse of Art* (1974), and *The Culture We Deserve: A Critique of Disenlightenment* (1989)

Aspects of popular culture, sympathetically appreciated: *God's Country and Mine: A Declaration of Love, Spiced With a Few Harsh Words* (1954), *The Delights of Detection* (1961), and *A Catalogue of Crime* (1971)

Biography: *Berlioz and His Century: An Introduction to the Age of Romanticism* and *A Stroll With William James* (1983)

These works led to his magnum opus, *From Dawn to Decadence: 500 Years of Western Cultural Life, 1500 to the Present* (2000), published at the age of 93. It is an innovative, comprehensive work on the codes of feeling and conduct in the thought and learning of the modern West.

Many of Barzun's other publications concerned "the state of the language" and "the means and objects of communication." These cultivated the value of literacy for the work of intellect.

The Modern Researcher (1957 and later editions)

Follett's Modern American Usage (1966)

On Writing, Editing, and Publishing (1971)

A Word or Two Before You Go: Brief Essays on Language (1986)

Simple and Direct: A Rhetoric for Writers (1975)

Other books dealt with "the supplies of money for thought and learning," not simply their scale and source but also how the supplies could best serve the intellect:

Science: The Glorious Entertainment (1964)

The American University: How It Runs, Where It Is Going (1968)

Clio and the Doctors (1974)

Last, Barzun consistently expressed his commitment to clear and disciplined instruction; to effective, unencumbered teaching; and to curriculum that imparts the skills of intellect to all children:

Teacher in America (1945)

Begin Here: The Forgotten Conditions of Teaching and Learning (1991)

*What Is a Schoo*l? and *Trim the College!* (2002)

Among Barzun's many awards, in 2007, his hundredth birthday, he received the 59th Great Teacher Award from the Society of Columbia Graduates, a fitting recognition of his service in the house of intellect.

Human Capital Theory and Education

The notion of human capital in economics is associated with the names of the Nobel laureate Gary Becker (University of Chicago; born in 1930) and Jacob Mincer (Columbia University; 1922–2006). Their main contribution was to consider the decision to pursue schooling as an investment decision, which is different from consumption decisions.

Most students attend school because they are compelled to, especially at the early stages; however, a fraction of students may do so because they enjoy acquiring new knowledge or because of the social status associated with it. In both cases, we are unable to explain why a small proportion of individuals are willing to invest a large amount of money in order to attend prestigious colleges. Similarly, we are also unable to explain why the group of tertiary educated is socially selected (in terms of parental education, income, and/or wealth). If it were just a matter of tastes, the standard approach to consumption would predict that the more educated would have been those youngsters who attribute less value to leisure (and who, therefore, would suffer less in renouncing things such as sporting activity and game playing).

There is of course some truth in this perspective—as for any consumption commodity, the demand increases with disposable income and decreases with the relative price. Richer people demand more education, but the overall demand decreases at later stages of education (since these are more expensive). This explanation, however, is at odds with the fact that people attend schools at earlier stages of their lives despite being richer at later stages.

Here is where the notion of schooling as an investment proves its value in accounting for these observed behaviors. The basic economic underpinning for any investment decision is giving up current opportunities in exchange for future advantages—an investor renounces current consumption in exchange for greater consumption in the future. In the case of educational choices, current income opportunities are renounced in exchange for better income prospects in the future. The decision to remain a student (especially at the secondary or tertiary level) is compared with the alternative of immediate entry into the labor market; and the opportunity cost of forgone income (namely, the potential earnings of working if one forgoes further education) are compared with the future prospects of the wages to be earned as a more highly educated worker.

Thus, the time spent in school (and the correlated amount of knowledge that is presumed to be accumulated) is the resource that is invested by any individual who aims to improve his or her future income prospects. This choice is undertaken under conditions of uncertainty, since no one knows what the labor market situation will be in the near future. For this reason, people rely on expectations by observing the existing wage differential in the labor market. In the Organisation for Economic Co-operation and Development countries, the so-called college premium (namely, the percentage difference in earnings between tertiary-educated and upper secondary school graduates of the employed population between the ages 25 and 64) was 55% in the year 2010 (Organisation for Economic Co-operation and Development, 2012). Thus, any youngster completing secondary school has to compare the alternative of immediate entrance in the labor market (where additional knowledge is also accumulated through learning by doing) with spending three to five years in college, in exchange of an estimated increase by half of the earnings over the course of the working life.

In principle, this opportunity is open for unlimited school attendance; but the return on acquired human capital has to be recovered over the remaining working life. This is not in contradiction with the fact that most college graduates do not apply for a second or third degree, knowing that losing additional years out of the labor market would not be compensated for by the potential gains.

Under appropriate assumptions, one can estimate the expected return associated with an additional year of schooling. By comparing the income streams over the entire lives of two otherwise identical individuals, one can statistically obtain the internal rate of return that would make them indifferent between the two alternatives. This procedure is usually indicated in the literature as a *Mincerian wage equation*. It has been repeatedly estimated for many countries, age cohorts, genders, and ethnic groups; the results obtained are of the order of a 4 to 12 percentage point increase for any additional year spent in school.

Given the size of the premium, one may wonder why we do not observe a massive demand for schooling in every country and for every age group. The main economic explanation makes use of two concepts: (1) *ability endowment* and (2) *liquidity constraints*. The first one considers that the learning of additional knowledge takes place at different speeds for different individuals. Thus, the brightest students accumulate more knowledge in a given amount of time compared with the less able. In many respects, this is also true when we replace the notion of ability endowment with the notion of family background. Thus, the speedier a student is, the lower will be his or her cost for acquiring education, and other things being constant, she or he will stay in school longer. The other source of individual heterogeneity derives from different access

to financial resources: Postponing entrance into the labor market requires funding to provide support during the period of study. In addition, tertiary institutions charge tuition fees that also need to be financed. Financial markets are typically reluctant to provide such funding, since poor individuals can provide no collateral.

A final assumption supports the notion of human capital. Educated workers will earn higher wages if and only if they are more productive from the point of view of the potential employer. By inference, countries with more educated labor forces should experience higher incomes. Unfortunately, empirical evidence is rather inconclusive in this respect. One possible reason is associated with the distinction between *quantity* and *quality* of human capital. Given the increasing availability of data on student test scores, some authors have studied the correlation between gross domestic product and average students' achievements in the same countries, even controlling for the average years of schooling in the population. The underlying intuition is that just spending time in school does not necessarily translate into the acquisition of additional knowledge, for this depends on factors such as quality of the teachers and the school management. The empirical evidence does not contradict this intuition.

Overall, the human capital paradigm is nothing more than an analogy, though a convenient one. We do not have compelling evidence that education increases workers' productivity per se. In general, education induces self-sorting of individuals, who therefore differ not only with respect to the education they have acquired but also with regard to many other unobservable characteristics that may be valuable for a firm. Suppose, for example, that self-consciousness favors the acquisition of education, and for similar reasons reduces absenteeism among workers; firms, then, will demand self-conscious workers because they are more productive (i.e., they display less absenteeism), and the workers themselves will also be more educated.

This opens the door to the competing explanation for the positive correlation between schooling and earnings, which is found in the data: the *signaling theory.* In this framework, employers aim to attract abler workers, but ability is not observable. So if abler workers can find a way to signal this, and if their behavior cannot be copied without cost by less able workers, then in a condition of equilibrium, we should observe that abler workers emit such a signal (e.g., signaling that they possess a degree or a school certificate). According to this theory, then, education is worthless from a productive point of view, but it helps in the screening of individuals.

Identity and Identity Politics

Identity—who we are—is often taken for granted; our sex, gender, sexuality, race, ethnicity, nationality, and so on constitute "who we are" and make us ourselves. Social theory, however, problematizes this commonsense notion of identity by asserting that identity is inextricably bound up with social categories and social relations, categories and relations that are themselves caught up in each other. The emphasis is on the way the social world has an impact on and shapes identity.

A concern with identity in educational studies often is also a concern about a range of enduring inequalities and the way particular sorts of inequality are attached to particular identities—for instance, women and wages, or minority ethnic students and educational outcomes. The issues are not always straightforward. There is significant ongoing academic debate as well as political struggle over what actually counts as inequality, which groups are experiencing inequality, whether inequalities are getting better or worse, and how inequality can be measured. In relation to education, there has been sustained debate over whether race or social class is a key axis of inequality and whether girls really are outperforming boys, and, if they do, where and when they do so and whether this is an advantage that is sustained in later life. Even when the identity group of concern has been settled on, there can be further contestation over the mechanisms through which inequalities are produced, namely, about whether these are the result of structural, systemic, institutional, and/or professional practices or whether they are the result of the characteristics or properties of the groups themselves. This latter approach is criticized for suggesting deficits within the individuals, groups, or communities that face the inequality in questions—it is seen as a "blame the victim" approach. This entry discusses the rise of identity politics during the 1960s and 1970s, the tension between concepts of identity as the essence of a person or as a construct, constructionist and poststructural approaches to identity, and research on how identity categories create educational advantages and disadvantages.

Identity politics arise out of demands to address the inequalities experienced by particular identity groups. Historically, we can identify the movements for women's suffrage and the abolition of slavery as early instances of politics attached to identity. Identity politics took off, though, in the 1960s and 1970s, when the Black civil rights movement, second-wave feminism, and the gay and lesbian movement all engaged in political struggles over the inequalities their members faced. Often referred to as new social movements, groups engaged in identity politics make claims concerning legal rights and material redistribution, as well as social recognition and equal treatment. That is, these new social movements engage in both material and cultural politics; and the activities of these movements have coincided with struggles for self-determination or nationhood for indigenous and colonized peoples around the world. Here, claims to political and land rights are often tied to the demonstration of a particular identity that is not social or mobile but is fixed and inheres in the person in an

abiding way—that is, an identity that is the essence of the person. This highlights a significant tension in concepts of identity—identity as essence or identity as construct—and in identity politics—claims based on an essential identity or claims based on contesting the dominant meanings attached to an identity.

This tension suggests some of the limitations of constructionist approaches to identity, inequality, and politics. First, while new social movements have shown how apparent essences naturalize injustices and locate these in the "nature" of the groups concerned, the rejection of essence is not universally beneficial. Second, constructionist approaches deflect essences rather than wholly undercut them. Third, constructionist approaches do not in themselves ensure that responsibility for inequalities will be located in social contexts rather than in individuals. Finally, these movements are typically concerned with a single identity and do not account well for the relationship between the multiple identities an individual might possess. Conceptual and political interventions that follow the work of Kimberlé Crenshaw and call for attention to the intersectionality of identity categories have made a major contribution to addressing this last problem; but, with a range of conceptual approaches to these categories, intersectionality does not necessarily resolve these other problems.

Poststructural approaches to theorizing identity have offered a significant response to the problems of constructionism by foregrounding language and meaning, in particular as this is organized in bodies of knowledge, or discourses. A key argument made by poststructural thinkers such as Jacques Derrida and Hélène Cixous is that identity categories function as binary pairs where sociocultural meaning is set in hierarchical relationships: man/woman, White/Black, heterosexual/homosexual. There are two key points here. One is that while these binary pairs are hierarchical, they are mutually dependent; the meaning of each member of the binary depends on the other. This suggest the second key point—the meaning of the dominant member of a binary is suggested by what it is not, the subordinate other against which it is compared and over which it asserts itself; man is *not* woman. This exposes the fact that meaning is constantly deferred as further hierarchical pairs are recognized: phallus/uterus, hardness/softness, rationality/emotion. All this involves a fundamental challenge to the idea of an abiding identity—the "postmodern" self is "decentered." In this framework, the individual who is self-knowing and reflexive is produced by the knowledge about that individual and about individuals and populations that circulate in particular sociohistorical contexts. These knowledges are linked to and implicated in relations of power, and they are simultaneously individualizing (Michel Foucault's anatomo-politics) and totalizing (Foucault's bio-politics).

In this conceptual framework, identity categories are parts of the discursive repertoires that make and/or reject particular sorts of individuals. According to Foucault, the person is *subjectivated*; she or he is made subject to relations of power and simultaneously made as a subject. The subject's sense of self—his or her subjectivity and self-identification—depends on being recognizable to, and being offered recognition by, other subjectivated subjects and subjectivating discourses. Judith Butler extends this idea by considering the way "performatives"—utterances that make the thing that they name—make particular sorts of subjects. If we see the classifications that make up identity categories as performatives, we see that "girl" does not describe the girl; it makes her a "girl."

The move from identity to the subject signals a significant conceptual and allied political shift. This subject is subjected by and in relations of power, but she or he can also engage in performative politics that resist, and shift, the discourses that constrain herself or himself. This subject can act politically, but within the constitutive constraints of the discourses and relationships that offer him or her recognition. A performative politics pushes at the limits of recognition as it troubles and misappropriates performatives and insists on subordinated and silenced meanings. In queer politics, the issue is not "who" we *are* but what we *do* as we engage in practices that might *undo* the apparently self-evident identities imposed on us through the performative.

In education, this leads to conceptual and empirical research, including action research, which interrogates how the constraints of normative identity categories create educational advantages and disadvantages, and experiments with ways in which these normative modes and subjects can be exceeded and unsettled. These poststructural politics have supplemented the identity politics associated with new social movements, at least at the leading edge of theory and activism. Yet liberal pluralist approaches to identity and equality that make claims to inclusion and recognition inevitably create a new "outside." These approaches continue to dominate policy and mainstream politics, as

well as common sense. And poststructural politics are vulnerable to reappropriation by these liberal pluralist approaches.

In a move that further unsettles identity and sidesteps these reappropriations, the work of Gilles Deleuze suggests a politics that is antisubjectivation. This sees subjectivation as part of the assemblage of forces that produce social formations. This means that identity politics are already contained and leads Deleuze to think about other political forms including "lines of flight" and "becoming-revolutionary." Perhaps conversely, Judith Butler has turned her attention to the binary of the human and the not human. In the context of the War on Terror, she has asked whose life is recognized as human and whose life and death are recognized as "grievable," to understand how human life is constituted as precarious and how for some recognition as human is foreclosed. She suggests a politics that builds new collectivities concerned with the constitutive force of forms of governance. Current theoretical and popular concerns are also reengaging the biological and material. New Materialism takes up Deleuzian ideas to foreground the affective and bodily as well as the productive forces of nonhuman matter and objects. At the same time, neuroscience and genetics renaturalize the characteristics of individuals and population groups that constructionist theory and poststructural politics have sought to radically unsettle. While New Materialism and neuroscience have vastly different intellectual histories and agendas, they share a rejection of the discursively constituted subject as the central concern, agent, or locus of action. While the productive force of objects is unlikely to move to the core of public thinking, neuroscience and genetics are almost certainly going to be the crucible in which struggles over who we are and who we get to be are fought in the coming years.

IDEOLOGY

The term *ideology* refers to a system of ideas and beliefs that is dominant within a group or society, and that affects most if not every sphere of social interaction and organization within it—political, economic, scientific, educational, and cultural. Thus, the Nazis had an ideology, and so did the Communist Party in the former USSR (*Union of Soviet Socialist Republics),* and so, too, does the "Tea Party" on the right and the Democratic Party on the left in American politics. The term evolved during the last decade of the 18th century and has grown to have a wide range of epistemological, theoretical, and historical meanings and interpretations.

The origins of the concept ideology can be traced to 18th-century French philosophical thought. The term *idéologie* ("ideology") was coined by the French philosopher Destutt de Tracy in 1795 to

define ideas that were to be used in clarifying and improving public debate; in particular, he wanted to provide the necessary rational foundation for the critique of the dominant intellectual and political traditions that defined his era. He created the term by combining the Greek *idea* ("form") and *logos* ("knowledge"). During the 19th century, *ideology* was used by numerous philosophers and social thinkers in Europe, and the term now has numerous meanings and interpretations. Terry Eagleton (1991) refers to 15 possible senses of "ideology"; accordingly, on his account, the term *ideology* is difficult to define precisely, since it should be perceived as a text, woven of a tissue of different conceptual strands. Within this multiplicity of meanings, however, one stands out—the concept of ideology is closely connected with power, with domination, and with control and justification of a political system. It should be apparent that educational institutions play a significant role in promulgating a society's dominant ideology (see the work of Michael Apple)—and under some circumstances in fostering awareness and generating resistance (the work of Paulo Freire is a good example here).

The core sense of the term is quite apparent in Marxist and neo-Marxist writings where, from a class conflict and structural-functionalist perspective, "ideology" refers to a core set of ideas and values that consolidates and legitimates the existing economic system and relations between social classes. The main function of the ideas constituting the ideology is to maintain the status quo of the economically, socially, and politically stratified society.

Ideology in Marx

In the works of Marx and Engels, especially in *German Ideology* (written in 1845–1846 but published for the first time in 1932 by the Marx-Engels Institute, Moscow), the term *ideology* was defined as the "production of ideas, of conceptions, of consciousness" (Volume 1, Part I, A) and as the ideas of the ruling class: "The ideas of the ruling class are in every epoch the ruling ideas" (Volume 1, Part I, B). The term *ideology* also was linked to "false consciousness," or an erroneous perception of reality (which, of course, includes social arrangements and organizations)—in other words, Marx recognized that it was functional for the ruling class to promulgate "false consciousness" in individuals in the subordinate classes, by getting them to believe the accounts, arguments, and justifications that were part of the society's ideology. In a Marxian sense then, ideology signified a new way of explaining how the structure society—its social classes, institutions, and so on—had originated and had been maintained.

Ideology in Gramsci

Antonio Gramsci (1930), the Italian Marxist philosopher and political theorist, furthered the development of the concept of ideology by introducing his concept of hegemony, wherein the political power of ideology as a justificatory system of ideas is based on consensus rather than force or coercion exerted by a hegemonic, ruling class. The subordinate classes for some time had (in Gramsci's view) consented to their own domination rather than having been forced or coerced—the ideology had become accepted as painting a true picture of reality rather than being seen as a tool of oppression used by the ruling or hegemonic class. Eagleton (1991) suggests that Gramsci was "an historicist Marxist who believes that truth is historically variable, relative to the consciousness of the most progressive social class of a particular epoch" (p. 121). However, Nicos Poulantzas (a structuralist Marxist) argued that the nexus between the dominant ideology and a hegemonic class is indirect: It passes through the mediation of the total social structure, where the dominant ideology *reflects* that unity rather than *constituting* it. (It is worth noting that there are similarities with Plato's thought here; in his *Republic*, the ruling elite, the Guardians, justify the stratification of the society into three classes by promulgating a "noble lie," the myth that individuals are born with one of three metals in their character; at first, this story is greeted with disdain, but within several generations, it becomes accepted as a true account. It seems as if Plato not only hit on the notion of a justificatory ideology but also foresaw Gramsci's point about this eventually not having to be promulgated by coercion.)

Ideology in Mannheim

Mannheim (1936) used the term more systematically in his *Ideology and Utopia*, where he attempted to analyze the nexus between ideology and social relations, with reference to social classes. Mannheim used the term *ideology* to highlight the ideas that support the status quo of a given society. Mannheim has shifted the meaning of the term to include both "general" and "total" ideologies and argued that all ideologies derived from society and social interaction.

Ideology in Adorno and Marcuse

Theodor Adorno (1973), from the Frankfurt School of critical theorists, attempted to find and locate the essence of ideology by reexamining Marx's theory of commodities and the concept of exchange value. By focusing on the self and identity, Adorno and other critical theorists at the Frankfurt School maintained that identity was the "primal form" of all ideology (Adorno, 1973, p. 161). Similarly, Herbert Marcuse (1964), in his classic *One-Dimensional Man*, argued that commodities define one's social identity, followed by "absorption of ideology into reality" (p. 11), and that "the people recognize themselves in their commodities; they find their soul in their automobile, hi-fi set, split-level home, kitchen equipment" (p. 9).

Ideology in Althusser

The French Marxist philosopher Louis Althusser (1972) developed the concept of ideology further. In defining the term *ideology,* Althusser, influenced by Jacques Lacan, a noted French psychoanalytic theorist, suggested that ideology does not reflect reality as it exists but represents "the imaginary relationship of individuals to their real conditions of existence" (Althusser, 1972, p. 162). This implies that individuals, as social actors, receive their knowledge of who they are from how others respond to them. Lacan's seminal principle of "the dialectic of recognition" (between imaginary and real) influenced Althusser's redefinition of the term *ideology*. He argued that ideology controls individuals and societies through repressive state apparatuses, or ideological state apparatuses, consisting of major agencies of socialization (e.g., political education, religion, the family, the legal system, culture, and the mass media).

Ideology in Jameson

The more recent poststructuralist and postmodern reinterpretation of the term *ideology* is in the work of Fredric Jameson (1991). He, like other neo-Marxist theorists, was influenced by Jacques Lacan's distinction between reality and "the Real" to understand "ideology." He redefines ideology as "the representation of the subject's imaginary relationship to his or her real conditions of existence" (Jameson, 1991, p. 51). He argues that there are numerous ideologies or ideological dominants. Applying Raymond Williams's (1977) typology of ideologies—residual (traditional), emergent (new), and dominant (existing)—Jameson advocates such a model as necessary for a better and more coherent understanding of ideology as a cultural dominant.

Ideology and Its Functions

As a result of the rapid economic, political, and social change that takes place when society is in flux, individuals experience a crisis of identity and look for people or symbols that offer security, safety, and a sense of belonging. In such cases, the ideology can offer such individuals a new sense of identity and belonging, as it did for former citizens of the USSR after its collapse in December 1991 (see Function 5, below). The functions of ideology can be summarized as follows:

1. The first and defensive function of ideology, as the process of legitimation, as "meaning in the service of power," and as the "ways in which meaning serves to establish and sustain relations of domination" (Thompson, 1990, p. 5), is to legitimate, justify, and consolidate the power of a dominant social group or class.

2. The second function, in terms of Marxist and neo-Marxist reproduction theories, is the continual reproduction of economic relations, to maintain the continuous dominance of the ruling class.

3. As described by David Easton (1965), a third function is to offer individuals a sense of identity and belonging by providing "articulated sets of ideals, ends, and purposes, which help the members of the system to interpret the past, explain the present, and offer a vision for the future" (p. 290). Easton explains that ideology can be used as "ethical principles that justify the way power is organized, used, and limited and that define the broad responsibilities expected of the participants in the particular political relationship" (p. 292).

4. The fourth function of ideology, as "the integrated assertions, theories, and aims constituting a politicosocial program" (Geertz, 1964, p. 47), is used by leaders to justify their actions and policies and to imbue them with the values of truth and justice.

5. The fifth function of ideology, as political, economic, and cultural beliefs, is to offer a universal set of core values that help create a sense of consensus in the nation-building process and a sense of shared identity.

6. The sixth critical and future-oriented function of ideology is to give meaning and a sense of purpose to alternative groups challenging the state.

Immigrants, Education of

An immigrant is a person who has consciously decided to leave his or her country of origin and take up residence elsewhere, namely, a country of settlement, with the view to acquiring legal status and employment. Global markets and knowledge-based economies, and also political oppression and famine, are important driving forces of immigration around the world; but other motivations include marriage, family reunification, cultural affinity, and the pursuit of higher education. Though expressed in different forms, in the host countries immigration policies have to varying degrees of success endeavored to promote within immigrants strong cultural and national identities favored by the majority group.

Immigration can be observed on all continents, though here the focus will be exclusively on immigration as it occurs in the Western hemisphere. This focus is adopted because patterns of immigration more routinely move from East to West (and South to North) and because it undoubtedly is in the West that the most elaborate and varied responses to immigration have transpired and continue to do so, particularly in the educational sphere. Nowhere have immigration and its relationship to education been more exhaustively studied than in the United States, for reasons that will be obvious: Owing to its enormous size and population, and also its founding myths and ideals, for millions the United States continues to be the land of immigration par excellence. Accordingly, migration and immigration studies elsewhere borrow heavily both from theory and from data generated in the United States. Nevertheless, migration and immigration studies have become a discipline in their own right in Australia, Canada, New Zealand, and most European countries. This entry discusses theories about assimilation and acculturation, educational efforts to integrate immigrants, and theories about immigrant students' performance in school.

Though vocabulary choices sometimes vary, particularly between Europe and North America (the former preferring the language of *integration*), two central concepts warrant special attention: assimilation and acculturation. Classic *assimilation* theories postulated four distinct phases: contact, competition, accommodation, and ultimately assimilation (implying a jettisoning of one's previous cultural attachments in favor of the dominant norms). All host societies reasonably expect immigrants at a minimum to adopt a working knowledge of the dominant language, to embrace its laws and many of its cultural values, and finally to contribute in various ways to the local economy. But historically, assimilation often has entailed concerted efforts to discourage minorities from retaining their language, culture, and religion and the expectation that minority groups will integrate into the mainstream.

Classic assimilation theory, long portrayed as a straightforward linear process, is now passé. Groundbreaking work in the early 1990s by Portes and Zhou (1993) provided researchers with a

modified version they dubbed "segmented assimilation," and this model now dominates immigration and migration studies. The authors argued that adaptation to immigration was a two-way process; both the immigrant communities and the mainstream society undergo change. Furthermore, in adjusting to their new circumstances, immigrants and their children avail themselves of a variety of adaptive strategies. Some, partly owing to their skin color, social class background, language proficiency, and educational attainment, experience upward mobility by gradually assimilating into the mainstream, with many adopting middle-class norms. Others find ways of adapting not through assimilating into the mainstream but rather through "selective acculturation," entailing solidarity with one's own immigrant community or ethnic group (Portes, Fernández-Kelly, & Haller, 2005; Zhou, 1997).

Acculturation refers to "the dual process of cultural and psychological change that takes places as a result of contact between two or more cultural groups and their individual members" (Berry, 2005, p. 698). Though a great deal of variability can be observed, acculturation involves mutual adaptation and accommodation; it may also involve "reactive" elements. In other words, acculturation does not inevitably entail yielding to the dominant culture; it can also lead to more pronounced identity expressions that involve recovering, or even discovering, attachments that stand in contrast to mainstream cultural norms. For example, ethnic or religious identities may solidify and strengthen—rather than diminish over time—as part of the acculturation process. So while groups may accept and even excel at many external features deemed important for fitting in with the society of settlement, among them educational and economic success, strong cultural identities and attachments to the country of origin may even be accentuated as groups navigate their way in their adopted homeland. In some cases, customs and traditions are passed down for many generations without losing much of their cohesive function, even as younger generations feel less attachment to the country of origin, increasingly adopt the dominant language, and may either discard or transform other cultural practices.

Which processes occur and how they unfold will depend in part on the degree of conflict between the immigrant communities and the host society; owing to linguistic, cultural, religious, and sometimes social class differences, both conflict and disadvantage can arise that may or may not attenuate over time as immigrants adapt to mainstream norms. For example, in schools, a number of misunderstandings may occur or discriminatory actions taken against certain minority groups that initially produce failure. To the extent that members of a group experience discrimination and identify with other—perhaps indigenous—stigmatized groups, one may speak of "dissonant acculturation" or "cultural discontinuity" in terms of a downward spiral, the result often being stigma, disadvantage, and even social exclusion. Of course, none of these outcomes are automatic. Much depends on the institutional features and prevailing attitudes of the host society, the characteristics of the group in question, and, of course, the personal traits and motivations of individuals. Whatever the case, strategies of adaptation for immigrants to new contexts is inevitably a two-way street. Moreover, irrespective of the challenges and hurdles, most immigrant groups have proven quite proficient at adapting to their country of settlement to one degree or another.

Educating Immigrants

The challenges and opportunities associated with the education of immigrants predate modern school systems, though it certainly can be said that support for public schooling grew—for example, in Canada and the United States—as dominant (read White, Anglo-Saxon, Protestant) groups came to see the importance of integrating masses of disparate origin. Educational responses to the children of immigrants over time have been varied, and many responses are indistinguishable from efforts to address other minority groups. In North America, the rapid expansion of immigration encompassing immigrant and refugee populations from around the world, particularly since the 1960s, has led to a number of structural and curricular changes in schools, only some of which were explicitly aimed at immigrants. One example of a policy aimed at the children of immigrants was bilingual education, and as this increasingly fell out of favor, ESL (English as a second language) classrooms became more common. However, with few exceptions, neither has been a very effective instrument for addressing the interests or concerns of immigrants themselves. Nevertheless, most parents strongly prefer that their children learn to master the dominant language, as a means of getting ahead (Glenn, 1996; Olneck, 2009).

In both Europe and North America, various efforts have been made to implement intercultural encounters and to revise historical narratives to

make them more inclusive of the stories of indigenous and immigrant minorities, and in these ways promote "intercultural awareness" or "culturally responsive" teaching. Yet notwithstanding lip service given to multicultural goals at the level of policy, on the ground, there is very little evidence to suggest that alterations to the public school curriculum amount to much more than window dressing and stereotypical gestures (e.g., occasional celebrations of different cultural attire, food, and music). Where educational responses are more substantive, these often are in private contexts that have fewer curricular constraints and enjoy strong community support. The lack of substantive progress in both Europe and North America is due to several factors:

1. The socio-ethnic stratification of minority pupils both between and within schools
2. The sorting and selecting mechanisms schools use
3. The vagueness of learning objectives
4. Self-selection by peer group
5. The lack of adequate training of teachers and the lack of correspondence between a majority of teachers and their pupils in urban districts
6. Increased focus on testing and core subjects
7. Parental resistance
8. Severe budgetary constraints

Whatever the drawbacks and unsettled disputes, the first generation of immigrant children continue to grow up learning the language of the host country at school (to be sure, some better than others), though many continue to speak the language of their parents at home. For many children of immigrants, there is a dual frame of reference and a strong motivation to succeed given the sacrifices their parents have made. Many may even experience school more positively than other minorities actually born in the country. Meanwhile, others find themselves caught in a cultural dilemma: Unable to identify with the host country (except in crude consumerist terms) and also unable to identify with the country of their parents, with its traditional customs and folk religion, some experience great difficulties in developing the feeling that they belong (Bankston & Zhou, 2002; Matute-Bianchi, 1991; Perlmann, 1997). For some this leads to new hybrid identities, while for others the combination of disaffection and school failure creates a set of problems that are manifest more in some groups than in others.

Theoretical Responses

Many theoretical approaches applicable to the education of immigrants were not specifically developed with immigrants in mind but rather were focused on indigenous minority groups or descendants of slaves. Attempting to explain the reasons why certain minorities were falling behind at school, theories of cultural deficit in the 1960s quickly yielded to cultural difference alternatives, stressing diverse forms of cultural capital that are simply not valued in school. Others attempted to explain differential treatment of various working-class and minority groups in schools using the tools of Marxism, the resultant analysis being that schools reproduce the social-class backgrounds of their pupils owing to the organizational features of schools, the middle-class expectations of teachers, and the sorting and selecting mechanisms schools use. Eager to cast aside some of these rather determinist forecasts for working-class and minority students, and moreover, inspired by the work of Paulo Freire, resistance theories resurrected the centrality of *agency*. More recently, in response to high levels of segregation, a theory of "voluntary separation" has been developed, arguing that spatial concentrations of even stigmatized minority groups—many of which began as immigrant communities—can turn their segregation to their advantage when they resist, rearrange, and reclaim the terms of their segregated experience. Here, the success of immigrant and minority groups explicitly does not depend on integrationist strategies but rather maintains that communities and schools can be arranged that promote important forms of equality, enhancing well-being and self-respect. Furthermore, voluntary separation can facilitate the cultivation of civic virtues that promote the good of the community (Merry, 2013).

But there can be no doubt that the work of John Ogbu has left an imprint on the field of immigrant education like no other. He argued that to make sense of why some minority groups on average perform better or worse in school, one must look at the relevant variables *outside* the school. It is the *community forces* behind these students that illuminate general patterns in school success or failure. Community forces broadly describe how different groups perceive, interpret, and strategically respond to schooling in ways that correspond to their unique histories and adaptations to their minority status.

Ogbu's work is perhaps best known for a typology he created to describe different minority

orientations to dominant culture generally and to education specifically. Though developed to explain the situation of immigrants and other minorities in American culture, his typology has been reinterpreted and applied around the world. It consists of the following categories: *semivoluntary* minorities (e.g., asylum seekers), *autonomous* minorities (self-sufficient groups that no longer face high levels of discrimination), *voluntary* minorities, and finally *nonvoluntary* minorities. Ogbu focused most of his attention on the last two categories.

Roughly speaking, voluntary minorities, namely, immigrants, experience strong academic achievement for several reasons:

a. They are seeking opportunity and are optimistic about achieving it.
b. They have a dual frame of reference, one that casts their country of settlement in a more favorable light.
c. They hold the view that obstacles encountered, such as discrimination and prejudice, are temporary and can be overcome with tenacity and hard work.
d. The orientation toward the school and other social institutions is one of "pragmatic trust," that is, schools are seen as purveyors of the knowledge, skills, language, and behaviors necessary for social mobility. Accordingly, a kind of meritocracy is internalized by this group, enabling success.

Meanwhile, *involuntary minorities* (also named "caste-like minorities") describe persons either forcibly conquered (indigenous groups) or brought against their will to an alien context (slaves and their descendants). These groups have been stripped of their primary cultural traits and forcibly assimilated. "Oppositional" orientations and patterns, on Ogbu's theory, will be commensurate with the degree of negative experiences and distrust experienced. Owing to a long history of institutional racism, their experience with discrimination, and the perception that education will not yield a payoff in the labor market, many minorities fitting this category develop oppositional attitudes toward school and, together with similar peers, may even come to see certain markers of identity (e.g., speech patterns, unrecognized cultural traits, performance, and dress) as something to be maintained rather than surrendered to mainstream expectations.

Though Ogbu's typology is somewhat fluid and has come under considerable criticism, its influence on the field of immigrant education remains uncontested and its theoretical strength lies in its comprehensiveness and cross-national applicability in explaining school success and failure among different types of minority groups. Of course, as with all theories, many exceptions to the rule can be found, and as this applies to immigrants in particular, some immigrant groups do extremely well, while others do not, notwithstanding their "voluntary" characteristics. For critics, predicting educational outcomes simply is an elusive task owing to complex identities and attachments, as well as varied structural processes and interactions in school. But critics largely agree with Ogbu that any attempt to understand school success or failure must look at what happens *in* the school as well as *outside* the school. School characteristics certainly matter: the student–teacher ratio, demographic concentrations, the organizational structure, finance schemes, leadership, teacher qualifications and expectations, mobility rates, the curriculum, disciplinary procedures, peer groups, and so on. All of these make for a complex portrait of school life. But features outside the school matter just as much if not more: neighborhood characteristics (crime rates, safety, and public services), family characteristics (educational attainment, divorce, abuse, nutrition, intimacy, social aspirations, structured free time, first language, etc.), and cultural forces emanating from the group in question. Furthermore, the immigrant status (country of origin but also destination), generational status, size of the local community, and perceived or experienced prejudice also affect the overall quality of life and influence the opportunities one may or may not have. Other variables to consider include the degree of acculturation, the language used at home, relationships with teachers, the influence of peer groups, parental beliefs, modeling, and involvement with a child's education, and finally the level of trust and assent persons experience vis-à-vis the existing opportunity structures.

Indian Religious and Philosophical Traditions and Education

Indian philosophy and religion will initially seem alien to the outsider. However, behind the initial strangeness, there are shared concerns and common issues that can help us see familiar issues in new ways. Indian philosophy and religion include traditions that have their birth on the Indian subcontinent (including present-day India, Pakistan, Bangladesh, Sri Lanka, and Nepal)—omitting the transplanted traditions (Islam, Christianity, and Zoroastrianism). Hinduism, Buddhism, Jainism, and Sikhism are major Indian religions; there are nine major philosophical schools, or *darsanas*. This entry introduces basic elements of Indian philosophical and religious thought and briefly comments on the value of Indian philosophy for contemporary educational thought. Due to space restrictions, it will focus on classical Hindu and Buddhist traditions, saying little about Jainism and Sikhism, despite their importance.

Basic Overview

In general, Indian philosophy is practical, concerned with ameliorating suffering and attaining liberation. It is a means by which people try to achieve wisdom and thereby make life better—indeed, make it in part a spiritual quest. So while one can identify characteristically religious practices in all major Indian religions (e.g., rituals, prayer, charity, and meditation), the pursuit of knowledge through philosophical analysis is taken to be itself a form of religious activity. Yet the character of philosophizing—applying careful reasoning to solve abstract puzzles regarding the coherence and justification of fundamental concepts and principles—is fairly similar in Western and Indian traditions.

Central Concepts

While there is wide diversity in the religious and philosophical traditions of India, we can identify several shared concepts. Let us briefly examine some of the most important. These terms are Sanskrit in origin.

Karma. The term literally means "action" but is usually taken to refer to the idea that actions have effects. It can be seen as a metaphysical principle but in Jainism is taken to refer to a type of substance. Karma has ramifications during one's lifetime, but the effects of one's actions are supposed to last beyond one's earthly life. Indeed, the principle of karma holds that one's actions in this life will determine the form of life in which one will be reborn.

Samsara. It literally refers to wandering but is sometimes translated as reincarnation, rebirth, or transmigration. This can be misleading because reincarnation suggests entering a new body, as though

the soul or some other nonphysical element of the person takes on a body. The trouble with this interpretation is that Buddhism denies the existence of the soul as a permanent entity. Other non-Indian traditions have embraced the idea of rebirth, but every major Indian tradition accepts a version of the doctrine. The Hindu, Buddhist, Jain, and Sikh religions all conceive of the soteriological goal of their faiths as release from samsara.

Dukkha. It might seem that rebirth is something to be looked forward to, giving one another chance to live a human life, but there is no guarantee that one will be reborn as a human being. Furthermore, the general sense is that one strives to be free from life, which is fraught with suffering, or *dukkha*. *Dukkha* can be thought of as the unsatisfactoriness of life. So the prevailing view is that birth leads to an ongoing cycle of suffering, death, and rebirth, with occasional respites of pleasure.

Maya and Avidya. *Maya* refers to illusion and *avidya* to ignorance (*vidya* means knowledge, with the prefix *a-* serving to negate). We suffer from *avidya* because we are subject to maya. Illusions lead to ignorance; in the ordinary course of events, for most of us, we take the illusory to be the real and thereby remain ignorant. In some forms of Hinduism, the problem is that we take distinctions between the self and Brahman (the source and sustainer of the universe) to be real, whereas in Buddhism the problematic illusion is that we take the self and objects in the world to be permanent existents. In both traditions, the path to liberation will partly consist in seeing things correctly.

Dharma. Literally, the term means "order" but is usually seen as representing duty. In classical Hinduism, dharma is one of the central goals of life. There are three types of dharma; one can view these as foundations of Hindu ethics. First, there is *varna-dharma*, obligations that stem from one's social class: priestly (*Brahmin*), warrior (*Kshatriya*), merchant (*Vaishya*), or laborer (*Sudra*). Second, there is *Asrama-dharma*, duties stemming from one's stage of life: student, householder, forest-dweller, and *sannyasin* (complete renunciation). A third form of dharma, *Sadharana-dharma*, applies to all people. The *Manusmriti* (Laws of Manu), a seminal Hindu text, holds there to be 10 duties that apply to everyone: steadfastness, forgiveness, application, nonappropriation, cleanliness, repression of sensuous appetites, wisdom, learning, veracity, and restraint of anger. Later, two additional duties were added: *ahimsa* (not hurting) and *bhutahitava* (general benevolence to all creatures).

In Buddhism, the Pali term *dhamma* is understood to broadly refer to the teaching of the Buddha. So someone practicing Buddhism might well say that she is practicing the *dhamma*—indeed, many prefer this way of speaking to avoid the misapprehension that Buddhists worship Siddhartha Gautama, the historical Buddha.

Principal Religions and Philosophical Schools

Three of the Indian nine philosophical *darsanas* are referred to as "unorthodox," meaning that they do not accept the ancient Hindu scriptures, the Vedas and the Upanishads, as authoritative. The three unorthodox *darsanas* are the Caravaka (Indian materialist), Jain, and Buddhist. Note that Jainism and Buddhism are simultaneously religions and philosophical schools. There are six orthodox *darsanas*: Nyaya and Vaisesika, Samkhya and Yoga, and Vedanta and Mimamsa. Typically, they are paired as above, noting some affinity between the schools. The orthodox *darsanas* are called Hindu, due to their acceptance of the Vedas, but are not individually sects of Hinduism.

Hinduism is a great world religion, with a billion adherents, but there is no unique source of the faith, as with Christianity (Christ), Islam (Muhammad), or Buddhism (Gautama Siddhartha). It did not spring from a single source that was interpreted differently by different groups; rather, the term *Hindu* was originally applied to all indigenous religions from the subcontinent, including Jainism, Buddhism, and Sikhism. Later, it was applied to the religion we now think of as Hinduism.

Hinduism

While somewhat controversial, the best available historical and archaeological evidence suggests that Indian civilization is born of a meeting between two cultures: the urban and sophisticated Indus civilization, including the cities of Harappa and Mohenjo-Daro in the Punjab region of present-day Pakistan, and the agricultural Vedic culture, probably migrants from central Asia.

Vedic culture became dominant throughout most of the Indian subcontinent by the 4th century BCE. Its religious traditions were highly ritualistic, emphasizing maintenance of the natural order

through *yajña*, a fire sacrifice. Brahmin priests, who became very powerful owing to their knowledge and their purity, performed the rituals. In Vedic culture, there were three aims of life: (1) *dharma* (duty), (2) *artha* (success), and (3) *kama* (pleasure); and the *varna* system seems to have been embraced in the "Hymn to the Cosmic Person," which is in the earliest Vedic text, the Rigveda. The *varna* system got distorted into the caste system, with which India still struggles to some extent, although it is illegal. Outside all *varna* are the outcasts, variously called untouchables, Harijans, or Dalits. The *varna* system has religious roots, but the caste system, with more than 2,000 castes, is at best a system for the social and economic organization of the society.

Against this political, social, and religious background, the Upanishads were composed. The Upanishads advance a new vision, with a fourth ideal of human life, *moksa*, to go along with *dharma*, *artha*, and *kama*. The idea is that we attain *moksa* in liberation from *samsara*. This is achieved through deep knowledge of one's self, which is further seen as identical to Brahman, or Ultimate Reality. The basic insight is that *atman* is *Brahman*. One's deepest self, atman, is identical to Brahman. This discovery leads to further ideas: If this identity is true of one's atman, then it is likewise true of all other atman, including that of, say, Justin Bieber. So Justin Bieber too is identical with Brahman, and this implies that each person in her deepest self is identical with Justin Bieber in his deepest self. So the Upanishads suggest that despite the appearance of difference, there is a fundamental, deeper unity. Samsara is the consequence of not seeing the fundamental unity of all that exists. The Upanishads are clearly at odds with the prevailing Brahminism: If salvation is a matter of knowing one's deepest self, then what need is there of the fire rituals and of the priests who perform the rituals? One of the challenges here is that the Upanishads seem to propose an ethic of inaction; this problem is answered in the Bhagavad Gita.

The Bhagavad Gita at once presents an engaging story as well as a new conception of Hinduism. The story is of Arjuna, who is about to enter a battle to take back his rightful kingdom. Yet he is apprehensive because fighting will surely bring death, including to relatives on the other side. This is a moral dilemma, with two unattractive options, but fortunately his charioteer is the god Krishna! The advice of Krishna is very useful in helping one see a distinctively Hindu view of morality. First, within the context of samsara, the worries over killing are exaggerated. Those we kill are to be reborn, so the consequences of killing are not so bad. Furthermore, in Arjuna's case, indeed the issue is clear: He is a Kshatriya, a warrior whose dharma is to fight this just battle. However, Arjuna must fight solely because it is his dharma, not selfishly for attachment to the fruits of his work. This idea of *work without attachment* transformed Hinduism, probably in response to the Buddhist and Jain movements at that time.

Krishna goes on to suggest three paths to liberation: One is *jnana-yoga*, the path of knowledge familiar from the Upanishads. But this path would not suit everyone; for some, the second path of *karma-yoga*, fulfilling one's *dharma* as well as *yajña*, without attachment, is best. Yet there is a third path—*bhakti-yoga*—the path of devotion to Brahman in the form of the gods. Krishna offers himself as a suitable object of Arjuna's devotion.

Hindu Philosophical Darsanas

Philosophers who take the Vedas as authoritative still have much to disagree about, and a wide range of views have developed regarding metaphysical, epistemological, ethical, and religious matters. Space precludes a complete account, but we can note central elements in the main *darsanas*.

The major form of Hindu pluralism, Vaisesika, holds that reality is constructed out of nine distinctive substances, as well as qualities and relations. Reality is composed of substances: earth, water, fire, air, ether, time, space, atman, and *manas* (or "mind"). Vaisesika is usually combined with the Nyaya *darsana* of logic and epistemology, which articulates a sophisticated view of how we can know reality. These *darsanas* suggest a kind of scientific realism regarding the world, although the details of the metaphysics are problematic.

Dualism is best exemplified by Samkhya, which recognizes two substances: *purusa* and *prakrti*. *Purusa* is nonmaterial substance with which consciousness is constituted. Consciousness is not equivalent to mind; mind, or *jiva*, is a bonding of consciousness to *prakrti*, or matter. This bonding creates individual identities, but these identities will be eliminated in *moksa*. However, Samkhya holds that individual *purusa* are nevertheless distinctive entities. Justin Bieber and I do not share a *purusa*, on this view. The Samkhya view is usually combined with the practical *darsana* of Yoga.

Samkhya dualism may appear subject to some of the problems associated with Cartesian dualism, such as the challenge of interaction, but this is mitigated because there is no problem of *purusa* causing *prakrtri* to act; nor is there a problem of conservation of energy, as there is for the Cartesian. If mind is itself part of the material world, then mind does not really interact with an entirely distinct substance; instead, mind is itself part of the material world. Consciousness is aware of *prakrti,* and this awareness needs explanation, but there is no problem of *purusa* causing the body to act—because it does not!

Third, there are monist schools. There are several Vedanta (end of the Vedas) schools; here, we will consider two of the most well known. Advaita Vedanta holds that there is but one substance, Brahman. This position is associated with the great Indian thinker Adi Shankara (about 788–820 CE). He criticized the Samkhya picture of multiple but indistinguishable *purusa* because, with no distinguishing features, there would be no reason to believe that there are multiple *purusa*. (This reasoning depends on a principle close to Leibniz's identity of indiscernibles: If X and Y have no discernible differences, then X and Y are numerically identical.) Adi Shankara held that only Brahman is ultimately real and that all distinctions are mere appearances. This means that beneath the apparent multiplicity in the world, there is unity. The apparent multiplicity is *maya*, causing *avidya* and further rebirth.

One interesting consequence of Adi Shankara's monism is that he supposes that we can think of "levels of reality." Only Brahman is ultimate reality, but it can be experienced at different levels. A drunkard sees pink elephants, but these have no reality apart from their reality in his mind. The elephants one experiences in dreams have dream reality, but on awakening one knows that their reality is limited. Then, there are the elephants one sees in Jaipur. These have a greater reality, but still they are but manifestations of Brahman. We need not quibble over whether each elephant is real—in a sense, they all are, but not equally so. Furthermore, Adi Shankara seems to be led to a form of linguistic relativity, holding that it is simply our language that creates the distinctions we experience in the world—the language precedes the distinction.

Visistadvaita Vedanta, a school developed by Ramanuja (ca. 1017–1137 CE), offers a theistic version of Vedanta. Like Adi Shankara, Ramanuja believes in one ultimate reality (Brahman), but holds that it can be experienced in two ways: as God (in personal form) or as the world. Both are real, according to Ramanuja. Ramanuja's theistic Vedanta is probably more popular with ordinary Hindu believers, but intellectuals are often more attracted to Adi Shankara's school.

In the Vedanta *darsanas*, there is conceived to be a permanent substance referred to as the *atman.* One's atman is not really distinct from Brahman but is mistakenly taken to be so; liberation (*moksa*) requires becoming completely aware of the identity of atman with Brahman. This concept of atman is one of the central distinctions between Vedanta and Buddhism.

Buddhism

While there are several traditions within Buddhism, we can identify four central beliefs. First among these is the Buddha's *four noble truths*: (1) life is characterized by *dukkha*, (2) craving causes *dukkha*, (3) it is possible to be liberated from *dukkha* (*nirvana*), and (4) *nirvana* is achieved through the eightfold noble path. The eightfold noble path provides a general ethic for achieving nirvana: right wisdom, right intention, right speech, right action, right livelihood, right effort, right mindfulness, and right concentration.

Second, Buddhists generally hold to a doctrine of conditioned arising, which holds that each event is dependent on other events. Conditioned arising implies that there are no uncaused causes, nothing that exists independently of other events—which is why Buddhists are generally atheists. Conditioned arising leads to the third central teaching of emptiness.

We can distinguish two possible views here: One view is that all aggregate objects are empty—devoid of independent existence—but there are atoms of which all aggregate objects are composed. The Abhidharma school held to this view. The second view, epitomized by the Madhyamaka school of Nagarjuna, a philosopher of the 2nd century BCE, holds that all phenomena are empty. This is radical indeed, leading to the idea that there are no real objects but that all objects are conventional constructions—more accurately, objects are series of events that we often mistakenly take to be real in themselves.

The fourth central teaching is of *anatman.* This is sometimes misleadingly referred to as the teaching of "no self." *Anatman* is the idea that there is no permanent self. Rebirth, thus, is a matter of a causal relationship between current and future events, but

there is no substance in which these events occur. A common analogy is between a flame that exists on one candle but is transferred to another (as the first is extinguished); the flame is a series of events, but there is no substance that unifies the flame as the "same flame." The concept of *anatman* is initially quite astounding, but one can find similar ideas in Western thought, including in the work of John Locke and David Hume.

Of all the Indian philosophical positions, Buddhism is most attractive to Western intellectuals, as it seems to make few controversial metaphysical assumptions and may well be consistent with some views in contemporary physics. It also does not assume a creator God. However, Buddhism is a major world religion as well as a philosophical view, and practiced forms of the religion differ from the abstract philosophical theses presented above: In some forms, there are supposed to be multiple gods, and most Buddhists accept some form of the doctrine of rebirth, making it difficult for scientific realists to accept Buddhism.

Implications of Indian Thought for Educational Philosophy and Theory

A case can be made for the importance of studying the philosophical traditions of any culture, especially those very different from one's own. Such study serves to help us become aware of our own basic judgments regarding the world and our experience of it, partly by seeing them as not shared by others or as interpreted and applied differently by others. Studying other philosophical traditions disorients the thinker, causing reflection on one's own basic assumptions regarding reality, knowledge, and value. Indian philosophy may be particularly valuable for educational theorists.

Three areas are particularly relevant here. First, concepts of the self that are developed in Indian traditions help in challenging individualism. Views of the self in Indian thought could be contrasted with Western views that stress ideals such as autonomy and self-esteem. In Buddhism, the self is taken as a kind of useful fiction, and in Advaita Vedanta, it is taken as deeply interconnected with the self of others. In neither tradition could it straightforwardly be taken as the central focus of educational practice. So Indian philosophy and religion invite us to reconsider our assumptions regarding autonomy, independence, and the development of qualities such as self-respect and self-esteem.

Second, educational practice is often taken to involve the acquisition of knowledge. Skepticism has long been a challenge in Western epistemology but is not taken seriously by many educational theorists. Furthermore, if one were to espouse epistemological skepticism, then one would likely reject the claim that education implies acquiring knowledge. In Indian thought, contrarily, knowledge is taken as an ideal, but it is extremely difficult to achieve. This is not quite skepticism—knowledge remains an elusive possibility—but it does make it odd to think of the schoolteacher as concerned with the transmission of knowledge. Knowledge or enlightenment can be seen as an ultimate goal, but the use of knowledge as a criterion by which we can select curricular content will need some finesse. Overall, a version of educational pragmatism might be preferred.

Third, religious education is highly problematic for educators concerned about developing open-mindedness and avoiding indoctrination. However, in the Indian milieu, religion is less a matter of orthodoxy (right beliefs) than of orthopraxy (right practice). Conceiving of religion as forms of practice that lead to *nirvana* or *moksa* avoids the problem of imparting controversial doctrines as uncontroversial. One prays, meditates, worships, or performs rites as means that are tested by their power to move one forward, rather than because they express the Truth. Indeed, the Truth—if there is one—is the end point of the journey, not something taken on faith at the outset. So the religious teacher can see himself as imparting practices to the student rather than as imparting truths. These practices are refined or rejected as one moves forward; they are not intended to be sacrosanct.

This entry has focused on classical Indian thought. Little has been said of the important Jain and Sikh traditions or about more recent developments; and both Buddhism and Hinduism are highly diverse traditions that cannot be encapsulated in a short entry. Furthermore, Indian thought has modern and contemporary developments, often in response to or influenced by developments in Western thought. The Further Readings section suggests some sources to explore more recent developments in Indian philosophy. That said, it is clear that the study of Indian philosophy and religion helps us see educational philosophy in a new light.

Individual Psychology: Alfred Adler

Alfred Adler (1870–1937) was an Austrian medical doctor who founded the psychological school of thought known as *individual psychology.* Contrary to popular belief, Adler was not a Freudian or a neo-Freudian but rather one of the originators of the psychoanalytic viewpoint alongside Sigmund Freud. Although he did work closely with Freud for some time, Adler's genius required that he part ways with Freud to dedicate himself to the development of his own unique viewpoint. Unlike Freud, Adler was quite pedagogical in orientation and actively advocated for an individual psychological approach to education. In 1919, Adler opened his first child guidance clinic in Vienna. News of his template for a less authoritarian, more democratic approach to education began to spread, and he was soon invited to speak in the United States, where he would eventually move. Individual psychological education focuses on appealing to the student's creative power to embark on a cooperative journey of intellectual growth and character development.

The Basic Orientation

Individual psychology is anything but an individualist psychology. The term *individual* was chosen to stress the indivisibility of the human being. Adler's viewpoints on human development, experience, behavior, and personality are unabashedly holistic and relational. Individual psychology was a precursor to the emergence of numerous social and interpersonal approaches to psychology and pedagogy, such as attachment theory and existential-humanistic self-development theory.

Adler was ahead of his time in the sense that he was never to succumb to the lures of the so-called nature/nurture bifurcation. This is a testament to his holism. For Adler, the nature/nurture approach to human development amounted to black-and-white thinking in the form of a false dilemma. All human lives are subject to the causative influences of inheritance, social situation, and *creative power.* All three of these life dimensions are intimately intertwined in a dynamic fashion, and no one dimension is merely reducible to the other. For instance, Adler once noted in critical reference to the modern fascination with genetics and neurology that the brain is in fact the *instrument* rather than the *origin* of the mind. Thus, from the perspective of individual psychology, educators should not think about students as the mere by-products of genetics or even environmental conditions. Students are rather interactively involved beings in need of guidance in the art of living with others. The child's education is never left to fate, genetics, or the environment. At the same time, Adler did believe that the child's social situation has the strongest effect at the outset of development. Responsibility falls on the educator to appeal to the creative power or free artistic creation of the pupil. For Adler, to educate means to bring favorable social influences to bear on and to keep a sharp watch to see how the child uses all of his or her experiences of hereditary and educational influence in the event that intervention is necessary.

One should not mistakenly infer that Adler was naively idealistic about the child's potential for free artistic creation. On the contrary, he was acutely aware of the relative helplessness of the child in comparison with the adult, for which he employed the phrase *feelings of inferiority.* The desire to become

more competent and overcome feelings of inferiority has the potential to motivate the child into becoming a spontaneous and enthusiastically involved pupil so long as educators provide an environment that is caring without pampering, genuinely empowering, and inspirational. Adler held that one is only justified in speaking of the "free decisions" of a child on enlisting his or her investment in the health-conducive, cooperative aim that he termed *Gemeinschaftsgefühl*, or "social interest." According to Adler, a good teacher should do what a mother does, which is connect to the child and pique his or her *interest*. Education is a process of engaging students to ensure that they orient themselves ever outward toward the world, things, and other people.

On the whole, then, individual psychology stresses the idea that a child only really becomes a full-fledged *student* within an interpersonal field characterized by community feeling. Where the prospective student is pampered, he or she is prevented from becoming sensitive to the world outside his or her own self-interest. Similarly, an environment that places a high value on competition will only orient the prospective student in the direction of self-enrichment and self-enhancement. For the child to be transformed into a student means that he or she would have been spared the limitations imposed by self-preoccupation. As Adler noted, the best way to teach subjects is in coherence with the rest of life. Moreover, the most efficient and effective way to engage the student is through his or her favored sensory modalities. Adler held that a good teacher makes an effort to find out how the child looks at the world and which sense organ has occupied most of his attention and has developed to the highest degree.

Critique of American Education

Adler found human beings to be social creatures through and through. Accordingly, the key to a thoroughgoing education is the ability to foster a community feeling in students. For this reason, Adler believed that cooperation is the ideal outcome of a quality education rather than the vaguer ideal of love. Education is only finally successful when the child feels valuable not to himself but to the common welfare. At the same time, *real* community requires something more than mere tolerance or a blind conformity to social norms. According to individual psychological education, students should be taught *both* the subject matter and how to think for themselves. In other words, the job of schools is to increase cooperation and facilitate character education rather than intellectual growth alone. Education is responsible for not one but two outcomes: intellectual development and interpersonal prophylaxis (i.e., the prevention of social ills), for which parents, educators, and mental health professionals must all work together.

Given this twofold goal, Adler believed that American education lagged behind European education with regard to the character aspects of pedagogy. He was of the opinion that modern life had become too complicated for students to be left to their own devices when it comes to character education but the American educational system was guilty of just this sort of abandonment. As a result, Adler believed that American schools set students up for personal aggrandizement rather than authentic citizenry. In protest, Adler (1958) asserted, "We no longer wish to train children only to make money or take a position under the industrial system. We want fellow men. We want equal, independent and responsible collaborators in the common work of culture" (p. 157).

Cautions for Educators

Given the basic principles of individual psychology, Adler cautioned educators along several lines:

> Education should not be "specialized," focused on the individual to the extent that it threatens the development of social interest.
>
> Educators should use restraint when using IQ tests. Such tests should be used merely to gauge the student's vulnerable areas and initiate remediation. IQ should never be used as a means for educators to place limits on the student's learning potential and avoid taking responsibility for the student's progress.
>
> Students should not be subject to overcrowded classrooms, due to the potential for neglect and disempowerment.
>
> Educators should make every attempt to avoid having students repeat grades, due to its demoralizing effects.
>
> Educators should similarly attempt to avoid establishing separate classrooms for slow students for the same reason.
>
> Educators should become aware of the many ways in which coming from a lower-socioeconomic status home might interfere with the process of becoming a mature student.

INDOCTRINATION

The topic of indoctrination is relevant to educational theory and philosophy as it is widely viewed as an unacceptable process that is the antithesis of education. Knowing the features of indoctrination will enable educators to guard against any extreme ideology that could undermine their students' cognitive, affective, and behavioral development, and it also enables them to avoid using indoctrinatory techniques in their own classrooms. This entry briefly discusses the evolution of thinking about indoctrination; the concepts of indoctrination, an indoctrinated person, and indoctrinatory tradition; and the fundamental differences between indoctrination, enculturation, and brainwashing.

Historical Background

Etymologically, the word *indoctrination* is derived from the Latin *docere* ("to teach") and *doctrina* ("whatever is taught"). Although indoctrination simply means instruction, it obtained a negative connotation from the start of the 20th century owing to the prevailing sociopolitical conditions. Leading educators at that time, including progressive educationists, disparaged indoctrination by associating it with authoritarian education. They were particularly wary of the confessional approach commonly used in churches, and as the century wore on, they also were aware of the techniques used to bolster adherence to the Nazi and the Communist political/social systems. (Some social critics even flirted with the hypothesis that the foundational aspects of Western liberal democracy actually were being inculcated using techniques usually associated with indoctrination; and members of minority groups have made the same charge about the ideas that have helped foster their own inequitable treatment.) Since then, indoctrination has been viewed negatively, with philosophers—especially in the 1970s and 1980s—attempting to identify a set of necessary and sufficient conditions for indoctrination (see, e.g., Snook, 1972).

The Basis of Indoctrination

It is still a matter of controversy whether inculcation of a single belief (usually but not necessarily a false one) can be done in such a way that it should count as indoctrination. For example, if a student comes to hold the unshakeable belief that Germany is the oldest democracy in the world, is he or she a victim of indoctrination rather than of bad teaching? Some philosophers say that it depends on the intention of the teacher, others argue it depends on the method of instruction that was used, while yet others would say that indoctrination is only directed at producing a single-minded commitment to large-scale systems of belief rather than single beliefs.

This last case is fairly clear-cut and is of great concern in our contemporary world: It seems that indoctrination certainly (but perhaps not only) takes place when a person unshakably holds "control beliefs" that promote a totalistic ideology. The concepts of control beliefs and totalistic ideology deserve elaboration. *Control beliefs* are the core beliefs all human beings acquire in the natural process of enculturation, socialization, and education. These are psychologically strong beliefs that are cherished and integral to a person's life and personal identity. They are usually embraced by the person without question and are most resistant (but not completely impervious) to change. While all human beings hold to control beliefs as members of a community or society, an indoctrinated person subscribes to a special type of control belief—that which promotes a totalistic ideology.

According to Robert Jay Lifton (1991), a *totalistic ideology* is an extreme ideology that has a detrimental impact on a person's cognitive, affective,

and behavioral development. Cognitively, a totalistic ideology severely limits one's intellectual horizon by constricting the person to a simplistic and binary, "we versus you" worldview. Affectively, such an ideology incites an all-or-nothing emotional alignment through intense affection and loyalty for one's leaders and fellow group members, and a corresponding hostility and hatred toward those outside the group. What follows in behavior is a mobilization of extremist thoughts and destructive emotions to protect one's ideology, advance its cause, and eradicate all obstacles and enemies at all costs. Although a totalistic ideology is likely to be found in the religious and political domains, it can potentially exist in all disciplines.

An Indoctrinated Person

To further understand indoctrination, it is helpful to differentiate an indoctrinated person from one who is not. First, an indoctrinated person clings to an extremely small number of control beliefs, and the methods of instruction that have been used with this person have been adopted with the intention of producing this single-mindedness. For example, all external stimuli that have the potential to be held as challenging the control beliefs accepted by the indoctrinated person may have been deliberately removed by the indoctrinator(s); or an artificial environment has been assured where the indoctrinated person, usually isolated from his or her family and community, is exposed to only the beliefs privileged by the indoctrinator(s). The selected control beliefs are often expressed in abstract and metaphysical terms such as *God*, *truth*, *freedom*, and *progress*.

Second, the control beliefs of an indoctrinated person are so deeply embedded and held in such a psychologically strong manner that they have colonized this person's entire cognitive landscape. By channeling all energy to themselves, these control beliefs determine the person's identity and control his or her entire life, making the person interpret *everything* through the lens of the control beliefs. These beliefs stubbornly withstand external challenge and even distort reality by filtering all incoming stimuli and reinterpreting new information in alignment with and support of one's control beliefs. This is possible because the control beliefs are fortified by a small but carefully implanted and deeply embedded cluster of intertwined beliefs.

Third, an indoctrinated person's control beliefs screen and censure new inputs that challenge, or are inconsistent with, the existing control beliefs by forming new beliefs to reject them, such as "This thought is from the devil" or "Only unsaved/evil/ignorant people think like that." Consequently, the indoctrinated person develops intense affection and loyalty for "Us" and a corresponding hostility and hatred toward "Them." The end result is that the person, feeling privileged to have been "chosen," is obsessed with removing all hindrances—human and otherwise—to fulfill the "higher calling" to protect and propagate his or her ideology.

An Indoctrinatory Tradition

Indoctrination does not occur in isolation; it requires a community of believers who share the same tradition in which the control beliefs have become embedded. There are three essential characteristics of such a tradition.

First, the intention of the indoctrinator(s) to propagate a totalistic ideology must be present. In other words, there must be a deliberate, systematic, and sustained process by the indoctrinator(s) to implant control beliefs that advance a totalistic ideology.

Second, an indoctrinatory tradition is necessarily a closed tradition that prescribes and preserves a monolithic ideology for its members. By dogmatically insisting that it has a monopoly on the truth, it trumpets its own infallibility, resists genuine learning from other traditions, and censures alternative worldviews. In the process, it fosters closed-mindedness and undermines the basic social conditions for its members to grow and mature in their thought, emotions, and actions.

Third (and in the opinion of many philosophers, most important), an indoctrinatory tradition is one that incapacitates its members' development of *strong rationality and strong autonomy.* Such a tradition may grant its members *weak rationality*, in the sense that they are capable of giving reasons to support their beliefs by assuming the truth of their own tradition. But strong rationality is denied, as its members are prohibited from examining or critiquing the tradition itself, considering alternatives, and learning from other traditions. For the same reason, an indoctrinatory tradition may grant its members weak autonomy by giving them limited freedom to order their lives within the boundary of the tradition and even to decide the extent of their commitment to the tradition (e.g., as a community leader or just a follower). But such a tradition deliberately deprives its members the strong autonomy to decide

and live a life of one's own choosing after careful deliberation of the available options. Any attempt to question one's tradition and explore alternatives is likely to be branded by the indoctrinator(s) and fellow members as "immature," "unacceptable," "evil," and "sinful," thereby making the person feel guilty and ashamed for having strayed from the "right" path.

Indoctrination, Enculturation, and Brainwashing

It should be noted that indoctrination is not an "all-or-nothing" phenomenon. Rather, it is manifested in various forms and shapes and to varying degrees, ranging from mild to strong indoctrination. It may even overlap, at times, with enculturation and brainwashing. It is therefore helpful to distinguish indoctrination from enculturation and brainwashing.

The process of enculturation involves children or new members of a community learning about a tradition's control beliefs. These control beliefs define and frame the person's worldview and identity as a member of a community. But these beliefs are not held in such an extreme way that they become impervious to doubt. A healthily enculturated person is allowed and encouraged to inquire into and even revise one's control beliefs if necessary, as well as to interact with and learn from other traditions. The willingness and ability of a normally enculturated person to question one's own beliefs, consider alternatives, and order one's life autonomously are largely absent in an indoctrinated person. The latter is one who blindly clings to a totalistic ideology; that is, the person's cognitive, affective, and behavioral growth has been paralyzed.

As for brainwashing, it is simply a term used to denote an extremely intense form of indoctrination, akin to psychological conditioning. A brainwashed person is one in whom control beliefs have been so deeply embedded and are held so strongly that the person's former beliefs have been totally replaced by the control beliefs implanted by the indoctrinator(s). By greatly imperiling a person's intellectual, moral, emotional, and social development, brainwashing dehumanizes the person—the very reason that makes indoctrination so objectionable.

Insight Learning

Gestalt psychologists proposed insight learning as an explanation for the type of one-trial learning that they observed after people or animals engaged in active problem solving. Therefore, insight learning can be contrasted with association-based empiricist philosophies and behaviorist theories that propose that all learning occurs gradually through the repetitive co-occurrence of external stimuli. A useful way to illustrate the difference between these two perspectives is to contrast two different animal learning experiments from the early 20th century, when the concept of insight learning was developed.
